Preface

The typical user of a simulation package is someone who holds a PhD or an MSc, has several years of experience in modeling and simulation, and underwent thorough training to use the specific package. He or she typically works as a scientist in the R&D department of a big organization or as an academic researcher. Because the theory of simulation is complicated and the typical simulation package presents many options, it is up to the user to employ his or her expertise to validate the model and the simulation.

This means that a small group of simulation experts is servicing a much larger group of people working in product development, production, or as students studying physics effects. Simulation models are oftentimes so complicated that the person who implemented the model is the only one who can safely provide input data to get useful output. Hence the use of computer modeling and simulation creates a bottleneck in product development, production, and education.

In order to make it possible for this small group to service the much larger group, the Application Builder offers a solution. It enables simulation experts to create an intuitive and very specific user interface for his or her otherwise general computer model—a ready-to-use application. The general model can serve as a starting point for several different applications, with each application presenting the user with input and output options relevant only to the specific task at hand. The application can include user documentation, checks for “inputs within bounds”, and predefined reports at the click of a button.

Creating an application often requires a collaborative effort by experts within the areas of: physics, numerical analysis, programming, user-interface design, and graphic design.

To a reasonable extent, COMSOL’s Technical Support team can recommend physics and numerical analysis settings for your application. In addition, the COMSOL documentation and online resources can be of great help. For programming and design, the Technical Support team can provide very limited help. These are areas where your own development efforts are critical.

The Application Builder makes it easy for a team to create well-crafted applications that avoid accidental user input errors while keeping the focus on relevant output details.

We at COMSOL are convinced that this is the way to spread the successful use of simulation in the world and we are fully committed to helping make this possible.
Introduction

A COMSOL® application is an intuitive and efficient way of interacting with a COMSOL Multiphysics® model through a highly specialized user interface. This book gives a quick overview of the Application Builder desktop environment with examples that show you how to use the Form editor and the Method editor. Reference materials are also included in this book, featuring a list of the built-in methods and functions that are available. For detailed information on how to use the Model Builder, see the book Introduction to COMSOL Multiphysics.

If you want to check out an example application before reading this book, open and explore one of the applications from the Application Libraries in one of the Applications folders. Keep it open while reading this book to try things out. Only the Applications folders contain applications with user interfaces. The other folders in the Application Libraries are tutorial models with no user interfaces.

The Application Builder is included in the Windows® version of COMSOL Multiphysics and accessible from the COMSOL Desktop® environment. COMSOL Multiphysics and its add-on products are used to create an application. A license for the same add-on products is required to run the application from the COMSOL Multiphysics or COMSOL Server™ products.

Additional resources, including video tutorials, are available online at www.comsol.com.

RUNNING APPLICATIONS WITH COMSOL MULTIPHYSICS

With a COMSOL Multiphysics license, applications can be run from the COMSOL Desktop in Windows®, OS X, and Linux®.

RUNNING APPLICATIONS WITH COMSOL SERVER

With a COMSOL Server license, a web implementation of an application can be run in major web browsers on platforms such as Windows®, OS X, iOS, Linux®, and Android™. In Windows®, you can also run COMSOL applications by connecting to a COMSOL Server with an easy-to-install COMSOL Client, available for download from www.comsol.com. COMSOL Server does not include the Application Builder, Physics Builder, or Model Builder tools that come with the COMSOL Desktop environment.
GUIDELINES FOR BUILDING APPLICATIONS

If you are not experienced in building a graphical user interface or programming, you may want to read “Appendix F — Guidelines for Building Applications” on page 302.
The Application Builder Desktop Environment

MODEL BUILDER and APPLICATION BUILDER — Switch between the Model Builder and the Application Builder by clicking this button.

COMSOL DESKTOP ENVIRONMENT — The COMSOL Desktop environment provides access to the Application Builder, including the Form and Method editors, as well as the Model Builder.

APPLICATION BUILDER WINDOW — The Application Builder window with the application tree.

SETTINGS WINDOW — Click any node in the application tree, including those for form objects or methods, to see its associated Settings window.

The screenshot above is representative of what you will see when you are working with the Application Builder. The main components of the Application Builder desktop environment are:

- Application Builder window and ribbon tab
- COMSOL Desktop environment
- Form editor (see page 40)
- Method editor (see page 143)
THE APPLICATION TREE

The application tree consists of the following nodes:

- **Main Window**
- **Forms**
- **Events**
- **Declarations**
- **Methods**
- **Libraries**

The **Main Window** node represents the main window of an application and is also the top-level node for the user interface. It contains the window layout, the main menu specification, and an optional ribbon specification.

The **Forms** node contains subnodes that are forms. Each form may contain a number of form objects such as input fields, graphics objects, and buttons.

The **Events** node contains subnodes that are global events. These include all events that are triggered by changes to the various data entities, such as global parameters or string variables. Global events can also be associated with the startup and shutdown of the application.

The **Declarations** node is used to declare global variables, which are used in addition to the global parameters and variables defined in the model.

The **Methods** node contains subnodes that are methods. Methods contain code for actions not included among the standard run commands of the model tree nodes in the Model Builder. The methods may, for example, execute loops, process inputs and outputs, and send messages and alerts to the user of the application.

The **Libraries** node contains images, sounds, and files to be embedded in an MPH file so that you do not have to distribute them along with the application. In addition, the **Libraries** node may contain Java® utility class nodes and nodes for external Java® and C libraries.
THE FORM EDITOR

FORM TAB — The Form tab in the ribbon gives easy access to the Form editor.

FORM EDITOR WINDOW — The tabbed Form editor window allows you to move objects around by dragging. Click an object to edit its settings.

FORM OBJECTS — Each form contains form objects such as input fields, check boxes, graphics, images, buttons, and more.

SETTINGS and EDITOR TOOLS WINDOWS — Click any application tree node or form object to see its associated Settings window. The Editor Tools window is used to quickly create form objects.

Use the Form editor for user interface layout by creating forms with form objects such as input fields, graphics, and buttons.

The main components of the Form editor are:

• Form ribbon tab
• Application Builder window with the application tree
• Form window
• Editor Tools window
• Settings window
Creating a New Form

To create a new form, right-click the Forms node of the application tree and select New Form. You can also click New Form in the ribbon. Creating a new form will automatically open the New Form wizard.

If your application already has a form, for example form1, and you would like to edit it, you can open the Form editor in either of two ways:

- In the application tree, double-click the form1 node.
- In the application tree, right-click the form1 node and select Edit.
The Method editor

Method editor components:
- Method ribbon tab
- Application Builder window with the application tree
- Method window
- Model Expressions, Language Elements, Editor Tools, and Settings windows (these are stacked together in the figure above)

Use the Method editor to write methods for actions not covered by the standard use of the model tree nodes. A method is another name for what is known in other programming languages as a subroutine, function, or procedure.

The main components of the Method editor are:
- Method ribbon tab
- Application Builder window with the application tree
- Method window
- Model Expressions, Language Elements, Editor Tools, and Settings windows (these are stacked together in the figure above)
Creating a New Method

To create a new method, right-click the Methods node in the application tree and select New Method. You can also click New Method in the ribbon. Creating a new method will automatically open the Method editor. Methods created in this way are global methods and are accessible from all methods and form objects.

A sequence of commands associated with a button or menu item can be automatically converted to a new method by clicking Convert to New Method. Open the new method by clicking Go to Method. You can also create a method that is local to a form object by clicking Create Local Method. These options are shown in the figure below.

If a method already exists, say with the name method1, then you can open the Method editor in any of these ways:

- In the application tree, double-click the method1 node.
- In the application tree, right-click the method1 node and select Edit.
- Below the command sequence in the Settings window of a form object or an event, click Go to Method.
APPLICATION BUILDER PREFERENCES

To access Preferences for the Application Builder, choose Preferences from the File menu and select the Application Builder page.

You can configure the COMSOL Desktop environment so that the Application Builder is displayed in a separate desktop window. Select the check box Use separate desktop window for Application Builder.

Note that you can use the keyboard shortcuts Ctrl+Alt+M and Ctrl+Alt+A to switch between the Model Builder and Application Builder, respectively.

You can set an upper limit to the number of open Form editor or Method editor window tabs. Select the check box Maximum number of editors before closing and edit the number (default 15). Keeping this number low can speed up the loading of applications that contain a large number of forms.
The Application Builder and the Model Builder

Use the Application Builder to create an application based on a model built with the Model Builder. The Application Builder provides two important tools for creating applications: The Form editor and the Method editor. In addition, an application can have a menu bar or a ribbon. The Form editor includes drag-and-drop capabilities for user interface components such as input fields, graphics objects, and buttons. The Method editor is a programming environment that allows you to modify the data structures that represent the different parts of a model. The figures below show the Model Builder and Application Builder windows.

When creating an application, you typically start from an existing model. However, you can just as well build an application user interface and the underlying model simultaneously. You can easily, at any time, switch between the Model Builder and Application Builder. The model part of an application, as represented by the model tree, is called an embedded model.

The tools in the Application Builder can access and manipulate the settings in the embedded model in several ways; For example:

- If the model makes use of parameters and variables, you link these directly to input fields in the application by using the New Form wizard or Editor
Tools. In this way, the user of an application can directly edit the values of the parameters and variables that affect the model. For more information, see pages 49 and 77.

- By using the New Form wizard or Editor Tools, you can include a button in your application that runs a study node and thereby starts the solver. In addition, you can use this wizard to include graphics, numerical outputs, check boxes, and combo boxes. For more information, see pages 35 and 49.

- The Model Data Access tool and the Editor Tools window can be used to directly access low-level settings in the model for use with form objects or in methods. For more information, see pages 49, 88, and 148.

- By using the Record Code tool, you can record the commands that are executed when you perform operations within the model tree and its nodes. These will then be available in a method for further editing. For more information, see page 153.

**Parameters, Variables, and Scope**

The model tree may contain both parameters and variables that are used to control the settings of a model. The figure below shows the model tree of an application with nodes for both **Parameters** and **Variables**.

- Parameters are defined under the **Global Definitions** node in the model tree and are user-defined constant scalars that are usable throughout the Model Builder. That is to say, they are “global” in nature. Important uses are:
  - Parameterizing geometric dimensions
  - Specifying mesh element sizes
  - Defining parametric sweeps

- Variables can be defined in either the **Global Definitions** node or in the **Definitions** subnode of any model **Component** node. A globally defined variable can be used throughout a model, whereas a model component variable can only be used within
that component. Variables can be used for spatially or time-varying expressions, including dependent field variables for which you are solving.

In the Model Builder, a parameter or variable is a string with the additional restriction that its value is a valid model expression. For more information on the use of parameters and variables in a model, see the book *Introduction to COMSOL Multiphysics*.

An application may need additional variables for use in the Form editor and the Method editor. Such variables are declared in the Application Builder under the Declarations node in the application tree. The figure below shows the application tree of an application with multiple declarations.

The declared variables in the Application Builder are typed variables, including scalars, arrays, Booleans, strings, integers, and doubles. Before using a variable, you have to declare its type.

The fact that these variables are typed means that they can be used directly in methods without first being converted using one of the built-in methods. This makes it easier to write code with typed variables than with parameters and variables representing model expressions. However, there are several tools available in the Application Builder for converting between the different kinds of variables. For more information, see pages 124 and 285.
Running Applications

With a COMSOL Multiphysics license, applications can be run from the COMSOL Desktop environment. With a COMSOL Server license, applications can be run in major web browsers on a variety of operating systems and hardware platforms. In addition, you can run applications by connecting to COMSOL Server with an easy-to-install COMSOL Client for Windows®.

The following two sections explain how to run applications from the COMSOL Multiphysics and COMSOL Server environments. The third section, “Publishing COMSOL Applications” on page 33, describes your rights to publish applications.

Running Applications in COMSOL Multiphysics

In COMSOL Multiphysics, you run an application using any of these ways:

• Click Test Application in the ribbon or in the Quick Access Toolbar.
• Select Run Application in the File menu or in the Quick Access Toolbar.
• Double-click an MPH file icon on the Windows® Desktop.
• Select Test in Web Browser in the ribbon.

Testing an Application

Test Application is used for quick tests. It opens a separate window with the application user interface while keeping the Application Builder desktop environment running.

While testing an application, you can apply changes to forms, methods, and the embedded model at run time by clicking the Apply Changes button. Not all changes can be applied at run time, and in such a case, you are prompted to close the application and click Test Application again.

To preview the layout of a form without running the application, click Preview Form in the ribbon.

When Test Application is used, all methods are automatically compiled with the built-in Java® compiler. Any syntax errors will generate error messages and the
process of testing the application will be stopped. To check for syntax errors before testing an application, click the **Check Syntax** button in the **Method** tab.

**Check Syntax** finds syntax errors by compiling the methods using the built-in Java® compiler. Any syntax errors will, in this case, be displayed in the **Errors and Warnings** window in the Method editor. For more information, see “The Method Editor” on page 143.

**RUNNING AN APPLICATION**

**Run Application** starts the application in the COMSOL Desktop environment. Select **Run Application** to use an application for production purposes. For example, you can run an application that was created by someone else that is password protected from editing, but not from running.

**DOUBLE-CLICKING AN MPH FILE**

When you double-click an MPH file icon on the Windows® Desktop, the application opens in COMSOL Multiphysics, provided the MPH file extension is associated with COMSOL Multiphysics. The application may either be opened for editing or for running. You control this behavior from the root node of the application tree. The **Settings** window for this node has a section titled **Application** in which you may select either **Edit application** or **Run application**. A change in this setting will be applied when you save the MPH file.

The option **Edit application** will open the application in the Application Builder.
The option Run application will open the application in runtime mode for production purposes. This option is similar to selecting Run Application in the File menu with the difference that double-clicking an MPH file will start a new COMSOL Multiphysics session.

If you have installed the COMSOL Client for Windows®, the MPH file extension may instead be associated with the COMSOL Client, and double-clicking an MPH file will prompt you to log in to a COMSOL Server installation.

**Testing an Application in a Web Browser**

Test in Web Browser is used for testing the application in a web browser. This functionality makes it easy to test the look and feel of the application when it is accessed from a web browser connected to a COMSOL Server installation.

You can choose which of the installed web browsers you would like the application to launch in. Test in Web Browser opens a separate browser window with the application user interface while keeping the Application Builder desktop environment running.

**Test Application vs. Test in Web Browser**

Test Application launches the application with a user interface based on Microsoft®.NET Framework components, whereas Test in Web Browser launches the application with a user interface based on HTML5 components. Test Application will display the user interface as it would appear when the app is run with COMSOL Multiphysics or COMSOL Server, provided the COMSOL Client for Windows® is used to connect with the COMSOL Server installation. Test in Web Browser will display the user interface as it would appear when the app is run with COMSOL Server, provided a web browser is used to connect with the COMSOL Server installation.

For testing the appearance and function of an application user interface in web browsers for OS X, iOS, Linux®, and Android™, a COMSOL Server installation is required.
The table below summarizes the different options for running an application.

<table>
<thead>
<tr>
<th>SERVER</th>
<th>CLIENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMSOL Multiphysics</td>
<td>Test Application</td>
</tr>
<tr>
<td>COMSOL Multiphysics</td>
<td>Test in Web Browser</td>
</tr>
<tr>
<td>COMSOL Multiphysics</td>
<td>Run Application</td>
</tr>
<tr>
<td>COMSOL Server</td>
<td>COMSOL Client for Windows®</td>
</tr>
<tr>
<td>COMSOL Server</td>
<td>Web Browser</td>
</tr>
</tbody>
</table>

The Server column represents the software components that perform the CPU-heavy computations. The Client column represents the software components used to present the application user interface.

**SAVING A RUNNING APPLICATION**

When you test an application, it is assigned the name `Untitled.mph` and is a copy of the original MPH file. This is not the case when running an application.

By default, the user of an application will not be prompted to save changes when exiting the application. You control this behavior from the root node of the application tree. The Settings window for this node has a section titled **Application** in which you may select the check box **Ask to save application when closing**, as shown in the figure below.

As an alternative, you can add a button or menu item with a command to save the application. For more information, see page 115.
APPLICATION LIBRARIES
From the **File** menu, select **Application Libraries** to run and explore the example applications that are included in the COMSOL installation. Many of the screenshots in this book are taken from these examples.
You run an application, or open it for editing, by clicking the corresponding buttons below the Application Libraries tree.

Applications that contain a model, but no additional forms or methods, cannot be run and only opened for editing. Applications that contain forms and methods are collected in folders named Applications.

The applications in the Application Libraries are continuously improved and updated. You can update the Application Libraries by clicking Update COMSOL Application Library below the tree.

Additional applications that are not part of the Application Libraries may be available from the COMSOL website in the Application Gallery. To find these applications, click the Application Gallery button below the tree. This will open a browser with the web page for the Application Gallery.

Each application has an associated thumbnail image that is displayed in the Application Libraries. In the COMSOL Server web interface, the thumbnail image is displayed on the Application Library page.
To set the thumbnail image, click the root node of the application tree. The Settings window has two options: Set from Graphics Window and Load from File.

The Load from File option allows you to load images in the PNG or JPG file formats. Choose an image size from 280-by-210 to 1024-by-768 pixels to ensure that the image displays properly as a thumbnail in COMSOL Multiphysics and COMSOL Server.

The Set from Graphics Window option automatically creates two thumbnail images:
- An image of size 280-by-210 pixels shown in the Settings window of the application tree root node and in the Application Libraries.
- An image of size 1024-by-768 used as the default title page image in reports and in the Application Libraries in COMSOL Server.

PASSWORD PROTECTION

An application can be password protected to manage permissions. You assign separate passwords for editing and running in the Settings window, accessible by clicking the root node of the application tree in the Application Builder window.
You must have permission to edit an application in order to create passwords for running it.

When you open a password-protected MPH file, for editing or running, a dialog box prompts you for the password:

To remove password protection, create an empty password.

The password protection is used to encrypt all model and application settings, including methods. However, binary data, such as the finalized geometry including embedded CAD files, mesh data, and solution data, is not encrypted.

**SECURITY SETTINGS**

When creating an application with the Application Builder, it is important to consider the security of the computer hosting the application. Both COMSOL Multiphysics and COMSOL Server provide a very similar set of security settings for controlling whether or not an application should be allowed to perform external function calls, contain links to C libraries, run MATLAB functions, access external processes, and more.

The security settings in COMSOL Multiphysics can be found in the **Security** page in the **Preferences** window accessed from the **File** menu. In COMSOL Server, they are available in the Preferences page in the COMSOL Server web interface if you
are logged in as an administrator. If you are not sure what security settings to use, contact your systems administrator.

Running Applications with COMSOL Server

COMSOL applications can be run by connecting to COMSOL Server from a web browser or a COMSOL Client for Windows®. The COMSOL Client for Windows® allows a user to run applications that require a LiveLink™ product for CAD, as described in “Running Applications in the COMSOL Client”.

Running applications in a web browser does not require any installation or web browser plug-ins. Running an application in a web browser supports interactive graphics in 1D, 2D, and 3D. In a web browser, graphics rendering in 3D is based on WebGL™ technology, which is included with all major web browsers.

Running Applications in a Web Browser

Using a web browser, you can point directly to the computer name and port number of a COMSOL Server web interface — for example, http://comsol-server-machine-url.com:2036, assuming that port number 2036 is used by your COMSOL Server installation. You need to provide a username and password to log in.
When logged in, the **Application Library** page displays a list of applications to run. Click **Run in browser** to run an application. Applications are run in separate tabs in the browser.
Limitations When Running Applications in Web Browsers

When you create applications to run in a web browser, make sure you use the grid layout mode in the Application Builder; See “Sketch and Grid Layout” on page 94. This will ensure that the user interface layout adapts to the size and aspect ratio of the browser window. For low-resolution displays, make sure to test the user interface layout in the target platform to check that all form objects are visible. Applications that contain resizable graphics forms may not fit in low-resolution displays. In such cases, use graphics with fixed width and height to make sure all form objects fit in the target browser window. Depending on the type of web browser and the graphics card, there may be restrictions on how many graphics objects can be used in an application. You can get around such limitations by, instead of using multiple graphics objects, reuse the same graphics object by switching its source.

When running in a web browser, the LiveLink™ products for CAD software packages are not supported.

When running COMSOL applications in web browsers for smartphones and certain tablets, not all functionality is supported. Typical limitations include the ability to play sounds or open documents. In addition, file upload and download may not be supported.

If the application allows the user to make selections, such as clicking on boundaries to set boundary conditions, running in a web browser is different from running in COMSOL Multiphysics or the COMSOL Client for Windows®. In a web browser, boundaries are not automatically highlighted when hovering. Instead, it is required to click once to highlight a boundary. A second click will make the selection. A third click will highlight for deselection and a fourth click will deselect. The process is similar for domains, edges, and points.

Running Applications in the COMSOL Client

As an alternative to using a web browser for running applications, the COMSOL Client for Windows® can be used to connect to COMSOL Server for running applications natively in the Windows® operating system. This typically gives better graphics performance and supports more sophisticated graphics rendering in 1D, 2D, and 3D. In addition, the COMSOL Client for Windows® allows running applications that require a LiveLink™ product for CAD, provided that the
COMSOL Server you connect to has the required licenses. You can open an application with the COMSOL Client for Windows® in two different ways:

- The COMSOL Server web interface will allow you to choose between running an application in a web browser or with the COMSOL Client for Windows®.
  
  If you try to run an application with the COMSOL Client in this way, but it is not yet installed, you will be prompted to download and install it.

- If you have the COMSOL Client for Windows® already installed, a desktop shortcut will be available. You can double-click its desktop icon and before you can use the COMSOL Client to run applications, you will be prompted to log into a COMSOL Server with a valid username and password. After login, the COMSOL Client displays a COMSOL Server web interface identical to that seen when logging in from a web browser.

Using the COMSOL Client, applications run as native Windows® applications in separate windows. For example, applications run in the COMSOL Client may have a Windows® ribbon with tabs. When run in a web browser, ribbons are represented by a toolbar.
In the figure below, the COMSOL Server web interface is shown (top) with an application launched in the COMSOL Client for Windows® (bottom).

**RUNNING COMSOL SERVER ON MULTIPLE COMPUTERS OR A CLUSTER**

COMSOL applications can be run on multiple computers or clusters in two main ways:

- By installing COMSOL Server with primary and secondary instances.
- By configuring one of the study nodes in the Model Builder for a particular cluster.
Primary and Secondary Instances

Running COMSOL Server on multiple computers using primary and secondary instances allows for more concurrent users and applications than a single computer instance (or installation). The main COMSOL Server instance is called primary and the other instances are called secondary. The primary server is used for all incoming connections — for example, to show the web interface or to run applications in a web browser or with COMSOL Client. The actual computations are offloaded to the secondary server computers. This type of installation has a major benefit: Applications do not need to be custom-built for a particular cluster. Load balancing is managed automatically by the primary server, which distributes the work load between the secondary servers.

Configuring a Study Node for Cluster Sweep or Cluster Computing

If you want to utilize a cluster for applications that require large parametric sweeps or high-performance computing power, then you can configure the Model Builder study node(s) of an application using the Cluster Sweep and Cluster Computing options. Note that for building such applications, you will need a Floating Network License. You can find more information on configuring a study node for clusters in the books *Introduction to COMSOL Multiphysics* and the *Reference Manual*. For running such cluster-enabled applications, you can use either COMSOL Server or a Floating Network License of COMSOL Multiphysics.

Publishing COMSOL Applications

The COMSOL Software License Agreement (SLA) gives you permission to publish your COMSOL applications for others to use, including commercially, with certain restrictions spelled out in the SLA available here: www.comsol.com/sla. This permission enables you to share your applications with others and to charge them for using your applications.

The user of an application that you make available will need access to either COMSOL Multiphysics or COMSOL Server with the necessary add-on products. For using an application with COMSOL Multiphysics, the user needs to belong to the same organization that purchased the COMSOL Multiphysics license. For more flexibility, you can set up a COMSOL Server installation and let users from around the world access your application. You just need to provide them with a
username and password to your COMSOL Server installation. Alternatively, the
users can purchase their own COMSOL Server license.

The COMSOL Application License, also available at www.comsol.com/sla,
further lets you modify applications available in the Application Libraries and
publish those modified applications for others to use; including commercially,
with certain restrictions spelled out in the Application License. This allows you to,
for example, use one of the applications in the Application Libraries as a starting
point for your own applications by adding or removing your own features.

If you wish to apply the Application License to Applications that you create, the
Application License contains instructions on how to do so. The Application
License also addresses how you can use terms that you choose for modifications
you make to applications available in the Application Libraries, while the original
portions of those applications remain available under the Application License.

If you use COMSOL Server to host and run applications, the SLA also gives you
permission to make time on your COMSOL Server License (CSL) available to
persons outside your organization to host and run applications that you are
publishing to others, subject to certain restrictions.
Getting Started with the Application Builder

**STARTING FROM A COMSOL MULTIPHYSICS MODEL**
If you do not have a model already loaded to the COMSOL Desktop environment, select File>Open to select an MPH file from your file system or select a file from the Application Libraries. Note that the files in the Applications folders are ready-to-use applications. All other files in the Application Libraries contain a model and documentation, but not an application user interface.

Once the model is loaded, click the Application Builder button in the ribbon Home tab. This will take you to the Application Builder desktop environment.

**CREATING A NEW FORM**
To start working on the user interface layout, click the New Form button in the Home tab. This will launch the New Form wizard.

The New Form wizard assists you with adding the most common user interface components, so-called form objects, to the first form of your application. It has three tabs:

- Inputs/outputs
Double-click a node or click the Add Selected button to move a node from the Available area to the Selected area. The selected nodes will become form objects in the application, and a preview of the form is shown in the Preview area to the right. The size as well as other settings for form objects can be edited after exiting the wizard. At the top of the wizard window, you can change the name and title of the form. For details see “The Individual Form Settings Windows” on page 41. You can also choose to exit the New Form window at this stage by clicking Done, and then manually add form objects.

The Inputs/Outputs Tab
The Inputs/Outputs tab displays the model tree nodes that can serve as an input field, data display object, check box, or combo box. Input fields added by the wizard will be accompanied by a text label and a unit, when applicable. You can make other parts of the model available for input and output by using Model Data Access (see page 88). Check box and combo box objects are only available in this way. For example, you can make the Predefined combo box for Element Size under the Mesh node available in the wizard by enabling it with Model Data Access.
In the figure below, three parameters, including Length, Width, and Applied voltage, have been selected to serve as input fields.

In the figure below, corresponding to a different model, three Derived Values nodes have been selected to serve as data display objects.
After exiting the wizard, you can edit the size and font color as well as other settings for input fields and data display objects.

The Graphics Tab

The **Graphics** tab displays the model tree nodes that can serve as graphics objects: **Geometry, Selection, Mesh, and Results**. In the figure below, two such nodes have been selected.

![Graphics Tab](image)

The Buttons Tab

The **Buttons** tab displays the model and application tree nodes that can be run by clicking a button in the application user interface. Examples of such tree nodes are **Plot Geometry, Plot Mesh, Compute Study**, and each of the different plot groups under **Results**. In addition, you can add buttons for **GUI Commands, Forms, and Methods**.
In the figure below, three buttons have been added: Plot Geometry, Plot Mesh, and Compute.

Using the Form editor, you can add buttons that run your own custom command sequences or methods.

**Exiting the Wizard**

Click **OK** to exit the wizard. This automatically takes you to the Form editor.

**Saving an Application**

To save an application, from the **File** menu, select **File>Save As**. Browse to a folder where you have write permissions, and save the file in the MPH file format. The MPH file contains all of the information about the application, including information about the embedded model created with the Model Builder.
The Form Editor

Use the Form editor for user interface layout to create forms with form objects such as input fields, graphics, buttons, and more.

The Forms Settings Window

The Settings window for forms is displayed when you click the Forms node in the application tree. It lets you change the overall appearance of forms with settings for Text color, Background color, Font, Font size, Bold, Italic, and Underline.

The default is that all new forms and new form objects inherit these settings when applicable.

In the figure above, and in some of the figures below, the Settings window is docked to the right of the Application Builder window. By default, the Settings window is docked to the far right in the Application Builder desktop environment.
The Individual Form Settings Windows

The figure below shows the **Settings** window for a form.

Each form has its own **Settings** window with settings for:

- **Name** used to reference the form in other form objects and methods.
- **Form Title** that is used in applications with several forms.
- **Initial size** of the form when used as a dialog box or when the **Main Window** is set to have its size determined by the form.
- **Margins** with respect to the upper-left corner (**Horizontal** and **Vertical**).
- Choices of when to store changes in dialog boxes (**Store changes**), see also “Showing a Form as a Dialog Box” on page 59.
- **Icon** shown in the upper-left corner of a dialog box.
• Choices of whether the form should be **Resizable** or not when used as a dialog box.
• Choices of whether to view sections as **Expandable** and whether they should be **Initially collapsed** (**Section Settings**).
• Table with the formatting of all columns and rows included in the form (**Grid Layout for Contained Form Objects**).
• **Appearance** with settings for **Text color**, **Background color**, and **Background image**.
• **Events** that are triggered when a form is loaded or closed. (**On load** and **On close**.)

Double-click a form node to open its window in the Form editor. Alternatively, you can right-click a form node and select **Edit**. Right-click a form window tab to see its context menu with options for closing, floating, and tiling form windows.

---

**Sketch and Grid Layout Modes**

The Application Builder defaults to sketch layout mode, which lets you use fixed object positions and size. The instructions in the section “The Form Editor” assume that the Form editor is in sketch layout mode unless otherwise specified. For information on grid layout mode, see “Sketch and Grid Layout” on page 94.

**Initial Size of a Form**

There are two options for the initial size of a form:
• **Manual** lets you enter the pixel size for the width and height.
• **Automatic** determines the size based on the form objects that the form contains. If you are using grid layout mode and there are columns or rows set to **Grow**, then the size is not defined by the form objects. In this case, the size is estimated using the Form editor grid size as a base point. (It will typically be slightly larger.) You can change the grid size by dragging the right or bottom border of the grid. For more information on grid layout...
mode, see “Grid Layout” on page 97.

### Form Editor Preferences

To access **Preferences** for the Form editor, choose **Preferences** from the **File menu** and select the **Forms** page.

The **Forms** section includes settings for changing the defaults for **Layout mode**, **Margins**, and **Sketch grid**.
**Form Objects**

**Positioning Form Objects**
You can easily change the positioning of form objects such as input fields, graphics objects, and buttons in one of the following ways:

- Click an object to select it. A selected object is highlighted with a blue frame.
- To select multiple objects, use Ctrl+click. You can also click and drag to create a selection box in the form window to select all objects within it.
- Hold and drag to move to the new position. Blue guidelines will aid in the positioning relative to other objects.
- In sketch layout mode, you can also use the keyboard arrow keys to move objects. Use Ctrl+arrow keys to fine tune the position.

In the figures below, a **Plot** button is being moved from its original position. Blue guide lines show its alignment relative to the unit objects and the **Compute** button.

**Resizing Form Objects**
To resize an object:

- Click an object to select it.
- Hold and drag one of the handles, shown as blue dots, of the highlighted blue frame. If there are no handles, this type of form object cannot be resized.
COPYING, PASTING, Duplicating, AND Deleting an Object

To delete an object, click to select it and then press Delete on your keyboard. You can also click the **Delete** button in the Quick Access Toolbar.

You can copy-paste an object by pressing Ctrl+C and Ctrl+V. Alternatively, you can right-click an object to get menu options for **Copy**, **Duplicate**, **Delete**, and more.

To paste an already copied object, right-click an empty area in the form and right-click again. Depending on the copied object, a **Paste** menu option will be shown. In the figure below, an **Input Field** has previously been copied and as a result, a **Paste Input Field** option is shown.
ADJUSTING POSITION AND SIZE BY THE NUMBER OF PIXELS

When in sketch layout mode, you can adjust the position and size of an object by typing the number of pixels in the Position and Size section of its Settings window:

- Click an object to select it. Make sure its Settings window is shown. If not, double-click the object or click the Settings button in the Form tab.
- Edit the numbers in the Position and Size section.

<table>
<thead>
<tr>
<th>Position and Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal alignment:</td>
</tr>
<tr>
<td>Vertical alignment:</td>
</tr>
<tr>
<td>Width:</td>
</tr>
<tr>
<td>Height:</td>
</tr>
<tr>
<td>Position x:</td>
</tr>
<tr>
<td>Position y:</td>
</tr>
</tbody>
</table>

The Position and Size section will have different options depending on the type of form object. For grid layout mode, there are additional settings for the position of the object with respect to rows and columns. For details, see “Sketch and Grid Layout” on page 94.

CHANGING THE APPEARANCE OF DISPLAYED TEXT

For form objects that display text, the Appearance section in the Settings window lets you change properties such as the text displayed, font, font color, and font size. For some form objects, such as a button, the size of the object will adapt to the length of the text string.
In the figure below, the **Settings** window for a text label object is shown where the font size and color is changed.

By using grid layout mode (see “Sketch and Grid Layout” on page 94) you can gain further control over the size of form objects, such as setting an arbitrary size for a button.

**Selecting Multiple Form Objects**

If you select more than one form object, for example, by using Ctrl+click, then the **Settings** window will contain a set of properties that can be shared between the selected objects. Shared properties will always originate from the **Appearance** section, the **Position and Size** section, or the **Events** section.

**The Name of a Form Object**

A form object has a **Name**, which is a text string without spaces. The string can contain letters, numbers, and underscore. In addition, the reserved names `root` and `parent` are not allowed. The **Name** string is used in other form objects and methods to reference the object. The path to the object is shown as a tooltip when hovering over the **Name** field in the **Settings** window.
**INSERTING FORM OBJECTS**

You can insert form objects in addition to those created by the *New Form* wizard. In the *Form* ribbon tab, select the *Insert Object* menu to see a listing of all available objects.

The remainder of this section, “The Form Editor”, only describes the types of form objects that are added by the *New Form* wizard. The form objects added by using the wizard may include:

- **Button**
- **Graphics**
- **Input Field**
- **Text Label** (associated with Input Field)
- **Unit** (associated with Input Field)
- **Data Display**

However, when using *Model Data Access* (see page 88), the following form objects may also be added:

- **Check Box**
- **Combo Box**
For more information on the check box, combo box, and other form objects, see “Appendix A — Form Objects” on page 180.

**Events and Actions Associated with Form Objects**

You can associate objects such as buttons, menu items, ribbon buttons, forms, and form objects with actions triggered by an event. An action can be a sequence of commands including global methods or local methods. Local methods are not accessible or visible outside of the objects where they are defined. The events that can be associated with an object depend on the type of object and include: button click, keyboard shortcut, load of a form (**On load**), close of a form (**On close**), and change of the value of a variable (**On data change**).

Using Ctrl+Alt+click on a form object opens its local method in the **Method** editor. If there is no method associated with the form object, a new local method will be created, associated with the form object, and opened in the **Method** editor.

**Editor Tools in the Form Editor**

The **Editor Tools** window is an important complement to the **New Form** wizard and the **Insert Object** menu for quickly creating composite form objects. To display the **Editor Tools** window, click the corresponding button in the **Main** group in the **Form** tab.
You can right-click the nodes in the editor tree to add the same set of form objects available with the **New Form** wizard.

![Editor Tools](image)

When a node is selected, the toolbar below the editor tree shows the available options for inserting an object. You can also right-click for a list of these options. Depending on the node, the following options are available:

- **Input**

  An **Input Field**, **Check Box**, **Combo Box**, or **File Import** object is inserted as follows:
  - Inserts an **Input Field** using the selected node as **Source**. It is accompanied by a **Text Label** and a **Unit** object, when applicable.
  - Inserts a **Check Box** using the selected node as **Source**.
  - Inserts a **Combo Box** using the selected node as **Source**. A choice list is automatically created, corresponding to the list in the node. This option is only available when used with **Model Data Access** (see page 88) to make the corresponding node available in the editor tree.
  - Inserts a **File Import** object using the selected node as **File Destination**.
• Output
  - Inserts a Data Display object accompanied by a Text Label when applicable.
  - Inserts a Results Table object when the selected node is a Table.
• Button
  - Inserts a Button object with a command sequence running the selected node.
• Graphics
  - Inserts a Graphics object using the selected node as Source for Initial Graphics Content.
• Edit Node
  - Brings you to the Settings window for the corresponding model tree node.

The Editor Tools window is also an important tool when working with the Method editor. In the Method editor, it is used to generate code associated with the nodes of the editor tree. For more information, see “Editor Tools in the Method Editor” on page 148.

**Button**

Clicking on a Button is an event that triggers an action defined by its command sequence. The main section of the Settings window for a button allows you to:

• Edit the form object Name of the button.
• Edit the Text displayed on the button.
• Use an Icon instead of the default rendering of a button.
• Change the button Size from Large to Small.
• Add a **Tooltip** with text that is shown when hovering over the button.
• Add a **Keyboard shortcut** by clicking the input field and entering a combination of the modifier keys Shift, Ctrl, and Alt together with another keyboard key. Alt must be accompanied by at least one additional modifier.

### Choosing Commands to Run

The section **Choose Commands to Run** lets you control the action associated with a button-click event. The figure below shows the **Settings** window for a button that triggers a sequence of four commands.
A menu, ribbon, or toolbar item will also provide a Choose Commands to Run section in its Settings window, and the functionality described in this section applies. For more information on using menu, ribbon, and toolbar items, see “Graphics Toolbar” on page 68, “The Main Window” on page 110, “Table” on page 250, and “Toolbar” on page 258.

To define a sequence of commands, in the Choose Commands to Run section, select a node in the editor tree. Then click one of the highlighted buttons under the tree, or right-click and select the command. In the figure below, the Geometry node is selected and the available commands Run and Plot are highlighted. Click Run to add a geometry-building command to the command sequence. Click Plot to add a command that first builds and then plots the geometry. The option Edit Node will take you to the corresponding node in the model tree or the application tree.

You do not need to precede a Plot Geometry command with a Build Geometry command (that you get by clicking Run). The Plot Geometry command will first build and then plot the geometry. In a similar way, the Plot Mesh command will first build and then plot the mesh.

The command icons highlighted for selection are those applicable to the particular tree node. This is a list of the command icons that may be available, depending upon the node:

- Run
- Plot
- Set Value
- Show
- Show as Dialog
- Import File
Some commands, such as the various plot commands, require an argument. The argument to a plot command, for example, defines which of the different graphics objects the plot should be rendered in.

The example below shows the Settings window and command sequence for a Compute button as created by the New Form wizard. This button has a command sequence with two commands: Compute Study 1 and Plot Temperature.

The Plot Temperature command has one argument, graphics1.
To add or edit an input argument, click the **Edit Argument** button below the command sequence, as shown in the figure below.

To reference graphics objects in a specific form, the following syntax is used: `/form1/graphics2, /form3/graphics1`, etc. If a specific form is not specified, for example, `graphics1`, then the form where the button is located is used.

To control the order and contents of the sequence of commands, use the **Move Up**, **Move Down**, and **Delete** buttons located below the command sequence table.
CONVERTING A COMMAND SEQUENCE TO A METHOD

A sequence of commands can be automatically converted to a new method, and further edited in the Method editor, by clicking **Convert to New Method**.

Open the new method by clicking **Go to Method**.
You can also create a method that is local to a form object by clicking Create Local Method. These options are shown in the figure below.

The method contains calls to built-in methods corresponding to the commands in the command sequence, as shown in the figure below.

In this example, the first line:

```java
model.study("std1").run();
```

runs the model tree node corresponding to the first study std1 (the first study node is called Study 1 unless changed by the user). The second and third lines:

```java
useGraphics(model.result("pg2"), "form1/graphics1");
useGraphics(model.result("pg1"), "form1/graphics2");
```

use the built-in method `useGraphics` to display plots corresponding to plot groups `pg1` and `pg2`, respectively. In this example, the plots are displayed in two different graphics objects, `graphics1` and `graphics2`, respectively.

For more information on methods, see “The Method Editor” on page 143.

**Setting Values of Parameters and Variables**

The Set Value command allows you to set values of parameters and variables that are available in the Parameters, Variables, and Declarations nodes. In addition, Set Value can be used to set the values of properties made accessible by Model Data.
Access (see page 88). The figure below shows a command sequence used to initialize a set of parameters and a string variable.

![Command sequence](image)

To learn how to perform the same sequence of operations from a method, click the Convert to New Method button under the command table.

**Changing which form is visible**

A button on a form can also be used to display a new form. This can be done in two ways. The first is to use the Show command, which will replace the original form with the new form. The second is to use the Show as Dialog command. In this case, the new form will pop up as a dialog box over the current form, and will usually request input from the user.
In the section **Choose Commands to Run**, you can select the **Show** command. The figure below shows the command sequence for a button with a command **Show form3**.

This command will leave the form associated with the button and make the specified form visible to the user.

**SHOWING A FORM AS A DIALOG BOX**

In order to use the **Show as Dialog** command, begin with the **Choose Commands to Run** section and select the form that you would like to show. The figure below
shows an example of the settings for a button with the command **Show form2 as dialog**.

With these settings, clicking the button in the application will launch the following dialog box corresponding to **form2**:
The *form2* window in this example contains a text label object and an **OK** button, as shown in the figure below.

In the **Settings** window, the **Dialog Actions** section has two check boxes:
- **Close dialog**
- **Store changes**

In the example above, the **Close dialog** check box is selected. This ensures that the *form2* window is closed when the **OK** button is clicked. Since *form2* does not have any user inputs, there is no need to select the **Store changes** check box.

Typical dialog box buttons and their associated dialog actions are:

<table>
<thead>
<tr>
<th>BUTTON</th>
<th>DIALOG ACTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
<td>Close dialog and Store changes</td>
</tr>
<tr>
<td>Cancel</td>
<td>Close dialog</td>
</tr>
<tr>
<td>Apply</td>
<td>Store changes</td>
</tr>
</tbody>
</table>

A dialog box blocks any other user interaction with the application until it is closed.

In order to control when data entered in a dialog box is stored, there is a list in the **Dialog Settings** section of the **Settings** window of a form where you can select
whether to store data **On request** or **Immediately** when the change occurs, as shown in the figure below.

- **Appearance**

  In the **Settings** window for a button, the **Appearance** section contains font settings as well as settings that control the state of the button object.

  - **Changing the Enabled and Visible State of a Form Object**

    Whether or not the button object should be **Visible** or **Enabled** is controlled from the check boxes under the **State** subsection. The **Appearance** section for most form objects has similar settings, but some have additional options; for example, input field objects.

    A button, or another form object, with the **Visible** check box cleared will not be shown in the user interface of the running application. A form object with the **Enabled** check box cleared will be disabled, or “grayed out”, but still visible. The state of a form object can also be controlled using built-in methods. For example, assume that a Boolean variable `enabled_or_disabled` is used to determine the enabled/disabled state of a button with **Name** `button3`. In this case, you can control the state of the button as follows:
setFormObjectEnabled("button3", enabled_or_disabled);

In a similar way, the call

setFormObjectVisible("button3", visible_or_not);

lets a Boolean variable `visible_or_not` control whether the button is shown to the user or not.

For more information, see “GUI-Related Methods” on page 291 and the Application Programming Guide.

**Graphics**

Each **Graphics** object gets a default name such as `graphics1`, `graphics2`, etc., when it is created. These names are used to reference graphics objects in command sequences for buttons, menu items, and in methods. To reference graphics objects in a specific form, use the syntax: `/form1/graphics2`, `/form3/graphics1`, etc.

**Selecting the Source for Initial Graphics Content**

In the **Settings** window for a graphics object, use the section **Source for Initial Graphics Content** to set the plot group to be displayed as default. To select, click **Use as Source** or double-click a node in the tree. If a solution exists for the displayed plot group, the corresponding solution will be visualized when the
application starts. The figure below shows the Settings window for a graphics object with a Temperature plot selected as the source.

In addition to Results plot nodes, you can also use Selection, Geometry, and Mesh nodes as the Selected source.

Selecting the check box Zoom to extents on first plot, positioned below the Selected source setting, ensures that the first plot that appears in the graphics canvas shows the entire model (zoom extents). This action is triggered once the first time that graphics content is sent to the graphics object.

APPEARANCE
For a graphics object, the Appearance section of the Settings window has the following options:

- Include an Icon, such as a logo image, in the upper-right corner.
• Set the background **Color** for 2D plots.
• Set a flat or graded background color for 3D plots by choosing a **Top color** and **Bottom color**.

In addition, the subsection **State** (not shown in the figure above) contains settings for the visible and enabled state of the graphics object. For more information, see “Changing the Enabled and Visible State of a Form Object” on page 62.

The figure below shows an application where the background **Top color** is set to white and the **Bottom color** to gray. In addition, the standard plot toolbar is not included.

**GRAPHICS COMMANDS**

In the editor tree used in a command sequence of, for example, a button, the **Graphics Commands** folder contains commands to process or modify a graphics
The available Graphics Commands are:

- **Zoom Extents**
  - Makes the entire model visible.

- **Reset Current View**
  - Resets the currently active view to the state it had when the application was launched; also see “Views” on page 72.

- **Scene Light**
  - Toggles the scene light (on or off).

- **Transparency**
  - Toggles the transparency setting (on or off).

- **Print**
  - Prints the contents of the graphics object.

Note that the commands Zoom Extents, Reset Current View, Scene Light, Transparency, and Print have corresponding toolbar buttons in the standard graphics toolbar. See the next section “Graphics Toolbar”.

**Plot While Solving**

To let the user monitor convergence, you can plot the results while solving. In this example, assume that the Plot option is enabled for Results While Solving. This
option is available in the **Settings** window of a **Study** node in the model tree, as shown in the figure below.

You can include a method that calls the built-in **sleep** method for briefly displaying graphics information before switching to displaying other types of graphics. Insert it in a command sequence after a plot command, as shown in the figure below.

In this example, the **sleep_a_bit** method contains one line of code:

```cpp
sleep(1000); // sleep for 1000 ms
```

For more information on the method **sleep**, see “sleep” on page 296.

In the command sequence above, the **Plot Velocity** command comes before the **Compute Study** command. This ensures that the graphics object displays the velocity plot while solving.

**Using Multiple Graphics Objects**

Due to potential graphics hardware limitations on the platforms where your application will be running, you should strive to minimize the number of graphics objects used. This is to ensure maximum portability of your applications. In addition, if you intend to run an application in a web browser, there may be
additional restrictions on how many graphics objects can be used. Different combinations of hardware, operating systems, and web browsers have different limitations.

In this context, two graphics objects with the same name but in different forms count as two different graphics objects. For example, form1/graphics1 and form2/graphics2 represent two different graphics objects. In addition, if a graphics object is used in a subform (see “Form” on page 220), then each use of that subform counts as a different graphics object.

To display many different plots in an application, you can, for example, create buttons, toggle buttons, or radio buttons that simply plot to the same graphics object in a form that does not use subforms.

If you need to use methods to change a plot, use the useGraphics command. For more information on writing methods, see “The Method Editor” on page 143. The example code below switches plot groups by reusing the same graphics object, based on the value of a Boolean variable.

```plaintext
if (my_boolean) {
    useGraphics(model.result('pg1'), "form1/graphics1");
    my_boolean=!my_boolean; // logical NOT to change between true and false
} else {
    useGraphics(model.result('pg2'), "form1/graphics1");
    my_boolean=!my_boolean;
}
```

**GRAPHICS TOOLBAR**

The type of tree node used in the Source for Initial Graphics Content determines the type of toolbar that is shown. The toolbar will be different depending on the space dimension and whether the referenced source is a Geometry, Mesh, Selection, or Plot Group node. For example, the Plot Group node displays an additional Show Legends button.

In the Settings window of a graphics object, in the Toolbar section, you can control whether or not to include the graphics toolbar, as well as its position (Below, Above, Left, Right).
**Graphics Toolbar for Geometry and Mesh**

The figure below shows the standard graphics toolbar as it appears when the **Geometry** or **Mesh** node, for a 3D model, is used as a **Source for Initial Graphics Content**.

![Graphics Toolbar for Geometry and Mesh](image.png)

**Graphics Toolbar for Selection**

When the **Source for Initial Graphics Content** is set to an **Explicit** selection, the graphics toolbar will contain three additional items: **Zoom to Selection**, **Select Box**, and **Deselect Box**. This is shown in the figure below (the **Deselect Box** is to the right of the **Select Box**).

![Graphics Toolbar for Selection](image.png)

For more information on selections, see “Selections” on page 74.

**Graphics Toolbar for Plot Groups**

The figure below shows the standard graphics toolbar as it appears when a **3D Plot Group** node is used as a **Source for Initial Graphics Content**.

![Graphics Toolbar for Plot Groups](image.png)

**Custom Graphics Toolbar Buttons**

In the Toolbar section, you can also add custom buttons to the graphics toolbar. Use the buttons under the table to add or remove custom toolbar buttons (items). You can also move toolbar buttons up or down, add a **Separator**, and **Edit** a button. The figure below shows a standard graphics toolbar for results with four additional buttons to the right.

![Custom Graphics Toolbar Buttons](image.png)
The figure below shows the corresponding table of graphics toolbar items.
To edit the command sequence for a toolbar item, click the **Edit** button to open the **Edit Custom Toolbar Button** dialog box.

This dialog box has settings that are similar to those of a button. For details, see “Button” on page 51.
Views
In the graphics toolbar, the **Go to Default 3D View** button (for 3D graphics only) will display a menu with all applicable views. The currently active view is indicated with a check mark.

In addition to a list of all views, there is an option **Reset Current View** that will reset the currently active view to the state it had when the application was launched.

**ANIMATIONS**
You can display animations in an application by creating a link to the graphics object that is used in the Model Builder as the **Subject** (source) for an **Animation**. You create such a link by following these steps:

- In the Model Builder, add an **Animation** node under the **Export** node using the **Player** option.
- Ensure that the **Target** is set to **Player** and the **Subject** is set to a plot group that is used as a **Source for Initial Graphics Content** for the graphics object where you wish to run the animation.
• Create a button, menu, ribbon, or toolbar item with a Run command applied to the Export Animation node.

Setting the Target as Player ensures that the animation is run in the same graphics window as the Subject plot group, instead of being exported to a file. The input argument to the Export Animation command can be used to specify in which graphics object the animation should be run. If the input argument is left empty, then the animation will be run in the same graphics window as the Subject plot group, if any. Note that this only applies if Target is set to Player.
Selections

Selections in the Model Builder

In the Model Builder, named selections let you group domains, boundaries, edges, or points when assigning material properties, boundary conditions, and other model settings. You can create different types of selections by adding subnodes under the Component > Definitions node. These can be reused throughout a model component.

As an example of how selections can be used, consider selections for boundary conditions. When you select which boundaries should be associated with a certain boundary condition, you can click directly on those boundaries in the graphics window of the COMSOL Desktop environment. This is the default option called Manual selection (see below). These boundaries will then be added to a selection that is local to that boundary condition. Named selections instead let you define global selections that can be reused for several different kinds of boundary conditions by just selecting from a drop-down list. The figure below shows an Explicit selection given the name Inlet Surfaces with two associated boundaries (22 and 88).
The figure below shows the **Settings** window for an **Inlet** boundary condition where the **Inlet Surfaces** selection is used. In this example, there is also an Outlet Surfaces selection.

For convenience, in addition to the **Manual** option, there is also a shortcut for **All boundaries**.

**Selections in the Application Builder**

The **Explicit** selection type lets you group domains, boundaries, edges, or points based on entity number, and is the type of selection most readily available for use with the Application Builder. You can allow the user of an application to interactively change which entities belong to an **Explicit** selection with a **Selection Input** object or a **Graphics** object. In the example below, the embedded model has a boundary condition defined with an **Explicit** selection. Both a **Selection Input**
object and a Graphics object are used to let the user select boundaries to be excited by an incoming wave.

The user can here select boundaries by clicking directly in the graphics window, corresponding to the Graphics object, or by adding geometric entity numbers in a list of boundary numbers corresponding to a Selection Input object.

To make it possible to directly select a boundary by clicking on it, you can link a graphics object to an Explicit selection, as shown in the figure below. Select the Explicit selection and click Use as Source. In the figure below, there are two Explicit
selections, Exciitation Boundary and Exit Boundary, and the graphics object graphics2 is linked to the selection Exciitation Boundary.

When a graphics object is linked directly to a selection in this way, the graphics object displays the geometry and the user can interact with it by clicking on the boundaries. The boundaries will then be added (or removed) to the corresponding selection.

To make it possible to select by number, you can link a Selection Input object to an explicit selection. For more information, see “Selection Input” on page 241. You can let a global Event be triggered by an Explicit selection. This allows a command sequence or method to be run when the user clicks a geometry object, domain, face, edge, or point. For more information on using global events, see “Events” on page 117 and “Source For Data Change Event” on page 120.

**Input Field**

An Input Field allows a user to change the value of a parameter or variable. In the New Form wizard, when a parameter or variable is selected, three form objects are created:

- A Text Label object for the parameter or variable description.
- An Input Field object for the value.
- A Unit object (if applicable) that carries the unit of measure.
By selecting a parameter or variable using the Editor Tools window, the same three form objects are created.

Assuming you do not use the Editor Tools window: To insert an additional input field, use the Insert Object menu in the ribbon and select Input Field. In the Form editor, you link an input field to a certain parameter or variable by selecting it from the tree in the Source section and click Use as Source. In the Source section of the Settings window, you can also set an Initial value. The figure below shows the Settings window for an input field.

In addition to parameters and variables, input fields can use an Information node as Source.
The default setting for the **Initial value** is **From data source**. This means that if the source is a parameter, then the initial value displayed in the input field is the same as the value of the parameter as specified in the Parameters node in the Model Builder. The other **Initial value** option is **Custom value**, which allows an initial value different from that of the source. If the **Editable** check box is cleared, then the **Initial value** will be displayed by the application and cannot be changed. You can add a **Tooltip** with text that is shown when hovering the mouse pointer over the input field.

The header of the **Source** section contains two buttons for easy access to tools that are used to make additional properties and variables available as sources to the input field.

The **Create New Variable and Use It as Source** button can be used to add new variables under the **Declarations** node. For more information, see “Declarations” on page 124. The **Switch to Model Builder and Activate Model Data Access** button can be used to access low-level model properties as described in the next section. For more information on **Model Data Access**, see “Model Data Access in the Form Editor” on page 88.

**DATA VALIDATION**

The **Data Validation** section of the **Settings** window for an input field allows you to validate user inputs with respect to units and values.

When creating an input field in the New Form wizard, the setting **Append unit to number** is used when applicable. This setting assumes that a user enters a number into the input field, but it can also handle a number followed by a unit using the COMSOL square bracket [ ] unit syntax. If the **Unit expression** is mm, then 1[mm] is allowed, as well as any length unit, for example, 0.1[cm]. An incompatible unit type will display the **Error message**. A parameter that has the expression 1.23[mm],
and that is used as a source, will get the appended unit mm and the initial value displayed in the edit field will be 1.23.
The Unit dimension check list has the following options:

- None
- Compatible with physical quantity
- Compatible with unit expression
- Append unit to number (default)
- Append unit from unit set

A value or expression can be highlighted in orange to provide a warning when the user of an application enters an incompatible unit, which is any unit of measure that cannot be converted to the units specified in the Data Validation settings. Enable this feature by selecting Compatible with physical quantity or Compatible with unit expression. In addition, the user will see a tooltip explaining the unit mismatch, as shown in the figure below.

![Figure showing unit mismatch](image)

If there is a unit mismatch, and if no further error control is performed by the application, the numeric value of the entered expression will be converted to the default unit. In the above figure, $9 \text{[kg]}$ will be converted to $9 \text{[m]}$.

A button Add Unit Label is available to the right of the Unit dimension check list.

![Data Validation settings](image)

Clicking this button will add a unit label to the right of the input field if there is not already a unit label placed there.

The None option does not provide unit validation.
Numerical Validation

The options **Append unit to number**, **Append unit from unit set**, and **None** allow you to use a filter for numerical validation of the input numbers.

The **Filter** list for the option **None** has the following options:

- **None**
- **Double**
- **Integer**
- **Regular expression**

The **Filter** list for the options **Append unit to number** and **Append unit from unit set** only allows for the **Double** and **Integer** options.

The **Double** and **Integer** options filter the input based on **Minimum** and **Maximum** values. If the input is outside of these values, the **Error message** is displayed. You may use global parameters in these fields. If global parameters are used, you can define such parameters with or without units. If you use global parameters without a unit, then only the numerical value of these parameters is considered when they are used as **Minimum** and **Maximum** values. For example, consider data validation of an input field for a length parameter \(L\) with unit cm. Further, assume that a global parameter \(L_{\text{max}}\) is used as the **Maximum** value. If you would like the maximum value of \(L\) to be 15 cm, then the following values for the parameter \(L_{\text{max}}\) will work: 15 (with no unit), 15[cm], 0.15[m], 150[mm], etc.

For the **Append unit from unit set** option, the **Minimum** and **Maximum** values are always with respect to the **Initial value** for the unit set by the unit set. For more information on unit sets, see “Unit Set” on page 136.

The **Regular expression** option, available when the **Unit dimension check** is set to **None**, allows you to use a regular expression for matching the input string. For more information on regular expressions, see the dynamic help. Click the help icon in the upper-right corner of a window and search for “regular expression”. For more advanced requirements, note that virtually any kind of validation of the contents of an input field can be made by calling a method using the **Events** section in the Settings window of an input field.
**Error Message**

You can customize the text displayed by the Error message. During the development and debugging of an application, it can sometimes be hard to deduce from where such errors originate. Therefore, when using Test Application, additional debugging information is displayed, as shown in the figure below.

The debugging information typically consists of the type of form object, the path to the form object, and the reason for the failure; for example, $5 \leq x \leq 10$.

No extra information is added when launching an application by using Run Application or COMSOL Server.

**Number Format**

The Number Format section contains a check box Use input display formatting. If selected, it enables the same type of display formatting as a Data Display object.

For more information, see “Data Display” on page 85.
**Appearance**

In addition to color and font settings, the **Appearance** section for an input field contains a **Text alignment** setting that allows the text to be **Left**, **Center**, or **Right** aligned.

Whether the input field should be **Visible** or **Enabled** is controlled from the check boxes under the **State** subsection. For more information, see “Changing the Enabled and Visible State of a Form Object” on page 62.

### Unit

In the **Settings** window for a **Unit** object, you can set the unit to a fixed string, or link it to an input field. Click the **Go to Source** button to the right of the unit **Label**.
list to show, in the form, the input field object to which it is linked. The figure below shows the Settings window for a unit object.

![Settings Window](Image)

When adding an input field using the New Form wizard, a unit object is automatically added when applicable. By default, the unit is displayed using Unicode rendering. As an alternative, you can use LaTeX rendering by selecting the LaTeX markup check box. Then, the display of units will not depend upon the selected font.

**Text Label**

A Text Label object simply displays text in a form. When adding an input field using the New Form wizard, a Text Label object is automatically added for the description text of the associated parameter or variable. There is a check box
allowing for Multiline text. If selected, the Wrap text check box is enabled. The figure below shows the Settings window for a Text Label object.

To insert an additional Text Label, use the Insert Object menu in the ribbon and select Text Label.

**Data Display**

A Data Display object is used to display the numerical values of scalars and arrays. If there is an associated unit, it will be displayed as part of the Data Display object.

**Source**

In the Settings window for a data display object, in the Source section, select a node in the model tree. Then click the Use as Source button shown below. Valid parameters, variables, and properties include:

- The output from a Derived Values node, such as a Global Evaluation or a Volume Maximum node
• Variables declared under the **Declarations > Scalar, 1D Array, and 2D Array** nodes
• Properties made available by using the **Model Data Access** tool; See “Model Data Access in the Form Editor” on page 88
• One of the following **Information** node variables, which are under the root node and under each Study node:
  - **Expected Computation Time**
    This is a value that you enter in the **Expected** field in the **Settings** window of the root node.
  - **Last Computation Time** (under the root node)
    This is the last measured computation time for the last computed study.
  - **Last Computation Time** (under a study node)
    This is the last measured computation time for that study.

When you start an application for the first time, the last measured times are reset, displaying **Not available yet**.

**USING THE NEW FORM WIZARD FOR GENERATING DATA DISPLAY OBJECTS**

In the New Form wizard in the **Inputs/outputs** tab, only the **Derived Values** nodes will generate **Data Display** objects. Variables under **Declarations** and constants made available with **Model Data Access** will instead generate **Input Field** objects.

When a **Derived Values** node is selected, two form objects are created based on the corresponding **Derived Values** node variable:
• a **Text Label** object for the **Description** of the variable
• a **Data Display** object for the value of the variable

The settings for these form objects can subsequently be edited. To insert additional data display objects, use the **Insert Object** menu in the ribbon and select **Data Display**.

**NUMBER FORMAT**

The **Number Format** section lets you set the **Precision**, **Notation**, and **Exponent**.
The figure below shows an example with data display objects for the variables Coil resistance and Coil inductance. A formatted unit label is automatically displayed as part of the object if applicable.

### RENDERING METHOD

By default, the unit of a data display object is displayed using Unicode rendering. As an alternative, you can use LaTeX rendering by selecting the LaTeX markup check box. Then, the data display does not rely on the selected font.

A formatted display of arrays and matrices is only supported with LaTeX rendering. The figure below shows a 2D double array (see page 132) displayed using a Data Display object with LaTeX markup selected.
You can add a **Tooltip** with text that is shown when hovering over the data display object.

---

**Model Data Access in the Form Editor**

The **Settings** window of many types of form objects has a section that allows you to select a node in a tree structure that includes the model tree, or parts of the model tree. Examples include the **Source** section of an input field or the **Choose Commands to Run** section of a button. There are many properties in the model tree that are not made available by default, because a model typically contains hundreds or even thousands of properties, and the full list would be unwieldy. However, these “hidden” properties may be made available to your application by a technique called **Model Data Access**.

The remainder of this section gives an introduction to using **Model Data Access**, with examples for input fields and buttons.

---

**MODEL DATA ACCESS FOR INPUT FIELDS**

By default, you can link input fields to parameters and variables defined in the model tree under the **Parameters** or **Variables** nodes and to variables declared in the application tree under the **Declarations** node. To access additional model tree node properties, click the **Switch to Model Builder and Activate Model Data Access** button in the header of the **Source** section of the input field settings window, as shown in the figure below.

![Switch to Model Builder and Activate Model Data Access](image)

You can also access it from the **Application** group of the **Home** tab of the Model Builder.
Then, when you click on a model tree node, check boxes appear next to the individual settings. In the figure below, the check box for an **Electric potential** boundary condition is selected:
The figure below shows the **Settings** window for an input field. The list of possible sources for this field now contains the **Electric potential**.

![Settings window for an input field](image)

**Model Data Access for Buttons**

Model Data Access can be used for buttons to set the value of a parameter, variable, or a model property. For example, you can create buttons for predefined mesh element sizes. The settings shown in the figure below are available when, in the **Settings** window of the **Mesh** node, the **Sequence type** is set to **User-controlled**.
mesh. In this example, the **Predefined** property for **Element Size** has been made available and then selected.
The figure below shows the Settings window for a button used to create a mesh with **Element Size > Predefined** set to **Fine**.

In the above example, a **Set Value** command is used to set the value of the **Predefined mesh size (hauto)** property. The property **Predefined mesh size (hauto)** corresponds to the following settings in the **Size** node shown earlier:

<table>
<thead>
<tr>
<th>Predefined Mesh Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extremely fine</td>
<td>1</td>
</tr>
<tr>
<td>Extra fine - Extra coarse</td>
<td>2-8</td>
</tr>
<tr>
<td>Extremely coarse</td>
<td>9</td>
</tr>
</tbody>
</table>
The value of the hauto property is a double and can take any positive value. For non-integer values, linear interpolation is used for the custom mesh parameters. You can, for example, let a slider object adjust the predefined mesh size. For more information on the slider object, see “Slider” on page 255.

In general, for individual model tree properties, you can quickly learn about their allowed values by recording code while changing their values and then inspecting the automatically generated code. For more information, see “Recording Code” on page 153.

You can also use a combo box object to give direct access to all of the options from Extremely fine through Extremely coarse. For more information, see “Combo Box” on page 188.

**SUMMARY OF MODEL DATA ACCESS**

The table below summarizes the availability of Model Data Access for form objects and events, as well as menu, toolbar, and ribbon items.

<table>
<thead>
<tr>
<th>FORM OBJECT, EVENT, OR ITEM</th>
<th>SECTION IN SETTINGS WINDOW</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input Field</td>
<td>Source</td>
</tr>
<tr>
<td>Button</td>
<td>Choose Commands to Run</td>
</tr>
<tr>
<td>Toggle Button, Menu Toggle Item, and Ribbon Toggle Item</td>
<td>Source and Choose Commands to Run</td>
</tr>
<tr>
<td>Check Box</td>
<td>Source</td>

<td>Source</td>
</tr>
<tr>
<td>Slider</td>
<td>Source</td>
</tr>
<tr>
<td>Toolbar (Toolbar Item)</td>
<td>Choose Commands to Run</td>
</tr>
<tr>
<td>Menu Item</td>
<td>Choose Commands to Run</td>
</tr>
</tbody>
</table>
A global event, menu, ribbon, or toolbar item provides a **Choose Commands to Run** section in its **Settings** window, to which the functionality described above in the section on buttons also applies. Global events and many form objects provide a **Source** section in its **Settings** window, and the functionality described above in the section on input fields applies. For information on global events, menus, ribbons, and toolbar items, see “Graphics Toolbar” on page 68, “The Main Window” on page 110, “Events” on page 117, “Table” on page 250, and “Toolbar” on page 258.

**Sketch and Grid Layout**

The Form editor provides two layout modes for positioning form objects: sketch layout mode and grid layout mode. The default is sketch layout mode, which lets you use fixed positions and sizes of objects in pixels. Use grid layout mode to position and size objects based on a background grid with cells. In grid layout mode, a form is divided into a number of intersecting rows and columns, with at most one form object at each intersection. This layout mode is recommended for designing a resizable user interface, such as when designing an application to be run in a web browser on multiple platforms.

**Sketch Layout**

Switch between sketch and grid layout mode by clicking **Sketch** or **Grid** in the **Layout** group in the ribbon.
The Sketch group in the Form tab has two options: Show Grid Lines and Arrange. The Arrange menu allows you to align groups of form objects relative to each other.

![Sketch Grid](image)

**Sketch Grid**

The Show Grid Lines option displays a sketch grid to which objects are snapped. Note that the grid used in sketch layout mode is different from the grid used in grid layout mode. The default setting for sketch layout mode is to show no grid lines. Without grid lines visible, a form object being dragged is snapped relative to the position of the other form objects.

If the Show Grid Lines option is selected, the upper left corner of a form object being dragged is snapped to the grid line intersection points.

![Sketch Grid Settings](image)

In the Settings window of the form, you can change the settings for the sketch grid:

- **Column width**
• **Row height**
• **Align grid to margin**
• **Snap zone**
  - A slider allows you to change the snap zone size from Small to Large.
• **Snap only to grid**
  - Clear this check box to snap both to the grid and the position of other form objects.

**Position and Size**

The sketch layout mode is pixel based, and the positioning of form objects is indicated as the coordinates of the top-left corner of the form object measured from the top-left corner of the screen. The x-coordinate increases as the object moves to the right, and the y-coordinate increases as the object moves from the top of the screen to the bottom. You can set the absolute position of a form object in the **Position and Size** section of its **Settings** window.

Form objects are allotted as much space as required, or as specified by their **Width** and **Height** values. Form objects are allowed to overlap.
GRID LAYOUT

Switch to grid layout mode by clicking **Grid** in the **Layout** group in the ribbon.

The buttons and menus in the ribbon **Grid** group give you easy access to commands for:

- Changing the row and column growth rules between **Fit**, **Grow**, and **Fixed**, which determine the layout when the user interface is resized (**Row Settings** and **Column Settings**).
- Inserting or removing rows and columns (**Insert** and **Remove**).
- Aligning form objects within grid cells (**Align**).
- Merging and splitting cells (**Merge Cells** and **Split Cells**).
- Extracting a rectangular array of cells as a subform and inserting it into a new form (**Extract Subform**).
- Defining the number of rows and columns (**Rows & Columns**).

**The Form Settings Window and the Grid**

After switching to grid layout mode, the form window shows blue grid lines.
To define the number of rows and columns, click the **Rows & Columns** button in the ribbon.

![Rows & Columns](image)

The section **Grid Layout for Contained Form Objects** in the **Settings** window shows column widths and row heights.

![Grid Layout for Contained Form Objects](image)

To interactively select a form, as displayed in the Form editor, click the top-left corner of the form.

![Interactive Selection](image)

A blue frame is now shown. To interactively change the overall size of a form, you can drag its right and bottom border. The form does not need to be selected for this to work.

Note that if you switch from sketch to grid layout mode, all rows and columns will have the setting **Fit** and the handles for the frame will not be displayed. If any of the rows and columns have the **Height** or **Width** setting set to **Grow**, then the frame will display handles for resizing in the vertical or horizontal direction, respectively.
The size of the interactively resized frame will affect the initial size of the form only if the initial size setting is set to Automatic. The size of the frame will also affect the initial size of the Main Window if its initial size setting is set to Use main form's size.

Rows and Columns
Click the leftmost cell of a row to select it. The leftmost cells are only used for selecting rows; form objects cannot be inserted there. When a row is selected, the Row Settings menu as well as the Insert and Remove commands are enabled in the ribbon tab. The figure below shows the fourth row highlighted.
Similarly, to select a column, click the cell at the top. This cell cannot contain any form objects. The figure below shows the third column highlighted. In this case, the **Column Settings** menu is enabled in the ribbon tab.

![Geometrical Dimensions](image)

<table>
<thead>
<tr>
<th>Prong length</th>
<th>75 mm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prong radius</td>
<td>2.5 mm</td>
</tr>
<tr>
<td>Base radius</td>
<td>5.5 mm</td>
</tr>
</tbody>
</table>

The **Row Settings** and the **Column Settings** have the same three options:

- **Fit** sets the row height or column width to the smallest possible value given the size of the form objects in that row or column.
- **Grow** sets the row height or column width to grow proportionally to the overall size of the form.
- **Fixed** sets a fixed value for the number of pixels for the row height or column width.

![Row Settings and Column Settings](image)

You can interactively change the row height and column width by dragging the grid lines.

![Grid lines](image)

In this case, the number of pixels will be displayed and the **Row Settings** or **Column Settings** growth policy will be changed automatically to **Fixed**.
As an alternative to changing the **Row Settings** or **Column Settings** from the ribbon, you can right-click in a row or column and select from a menu.

The menu shown when right-clicking a row or column also gives you options for inserting, removing, copying, pasting, and duplicating rows or columns.

**Cells**
Click an individual cell to select it. A selected cell is shown with deeper blue grid lines.

You can select **Merge Cells** and **Split Cells** to adjust the cell size and layout of your form objects.
When in grid layout mode, you can specify the margins that are added between the form object and the borders of its containing cell.

<table>
<thead>
<tr>
<th>Position and Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal alignment: Fill</td>
</tr>
<tr>
<td>Vertical alignment: Middle</td>
</tr>
<tr>
<td>Minimum widths: Manual</td>
</tr>
<tr>
<td>Height: 20</td>
</tr>
<tr>
<td>Row: 1</td>
</tr>
<tr>
<td>Column: 2</td>
</tr>
<tr>
<td>Row span: 1</td>
</tr>
<tr>
<td>Column span: 2</td>
</tr>
<tr>
<td>Cell margin: From parent form</td>
</tr>
<tr>
<td>Appearance: From parent form</td>
</tr>
</tbody>
</table>

In the **Settings** window of a form object, the **Position and Size** section has the following options for **Cell margin**:

- **None**
  - No cell margins

- **From parent form** (default)
  - The margins specified in the **Settings** window of the form; See “Inherit Columns and Cell Margins” on page 107

- **Custom**
  - Custom margins applied only to this form object

If the **Horizontal alignment** or **Vertical alignment** is set to Fill and the growth policy of the column or row allows the form object to be resized, then you can specify a minimum width or height, respectively. The minimum size can be set to **manual** or **automatic**. The **manual** option lets you specify a pixel value for the minimum size. The **automatic** option allows for a minimum size of zero pixels, unless the form object contents require a higher value. The minimum size setting is used at run time to ensure that scrollbars are shown before the form object shrinks below its minimum size.
Aligning Form Objects

The **Align** menu gives you options for aligning form objects within a cell. You can also let a form object dynamically fill a cell horizontally or vertically.

As an alternative, you can right-click a form object and select from a context menu.

### Drag and Drop Form Objects

You can drag and drop form objects to move them. Click a form object to select it, and then drag it to another cell that is not already occupied with another form object.
If you drop the object in an already occupied cell, then the objects switch places.

**Automatic Resizing of Graphics Objects**

In order to make the graphics object of an application resizable, follow these steps:

- Change the layout mode of the form containing the graphics object from sketch to grid layout mode.

- Change the **Height** setting for any row covering the graphics object to **Grow**. To change this, click the leftmost column of the row you would like to access. Then, change the **Height** setting in the **Settings** window of the form. Alternatively, right-click and select **Grow Row**.

- Change the **Width** for any column covering the graphics object to **Grow**. To change this, right-click the uppermost row of the column you would like to access and select **Grow Column**.

- Select the graphics object and change both the **Horizontal alignment** and **Vertical alignment** to **Fill**. You can do this from the **Settings** window or by right-clicking the graphics object and selecting **Align > Fill Horizontally** and **Align > Fill Vertically**.
Following the steps above, you may find it easier to make graphics objects resizable by performing grid layout mode operations, such as adding empty rows and columns as well as merging cells. If you are already in grid layout mode, then a graphics object will default to Fill in both directions.

**Extracting Subforms**

You can select a rectangular array of cells in a form and move it to a new form. First, select the cells by using Ctrl+click or Shift+click.

Then, click the Extract Subform button in the ribbon.
This operation creates a new form with the selected cells and replaces the original cells with a form object of type Form. In the Settings window of the subform, the Form reference points to the new form containing the original cells.
Inherit Columns and Cell Margins

By using subforms, you can organize your user interface, for example, by grouping sets of input forms. The figure below shows part of a running application with two subforms for **Beam dimensions** and **Reinforcement bars**.

![Subform Example]

For more information on adding subforms to a form, see the previous section and “Form” on page 220.

When aligning subforms vertically, as in the example above, you may want to ensure that all columns are of equal width. For this purpose, you can use the **Inherit columns** option in the **Settings** window of a subform. The figure below shows part of the **Settings** window for the **Beam dimensions** subform (left) with **Name geometry_beam** and for the **Reinforcement bars** subform (right) with **Name**
geometry_rebars. The geometry_rebars subform has its Inherit columns set to geometry_beam.

In the subsection Cell margins, you can specify the Horizontal and Vertical margins that are added between form objects and the borders of their containing cells. These settings will affect all form objects contained in the form, with their individual Cell margins set to From parent form; See “Cells” on page 101.

Copying Between Applications

You can copy and paste forms and form objects between multiple COMSOL Multiphysics sessions running simultaneously. You can also copy and paste within one session from the current application to a newly loaded application. In grid layout mode, a cell, multiple cells, entire rows, and entire columns may be copied between sessions.
When you copy and paste forms and form objects between applications, the copied objects may contain references to other forms and form objects. Such references may or may not be meaningful in the application to which they are copied. For more information on the set of rules applied when pasting objects, see “Appendix B — Copying Between Applications” on page 261.

When copying and pasting between applications, a message dialog box will appear if a potential compatibility issue is detected. In this case, you can choose to cancel the paste operation.
The Main Window

In the application tree, the **Main Window** node represents the main window of an application and is also the top-level node for the user interface. It contains the window layout, the main menu specification, and an optional ribbon specification.

**GENERAL**

The **Settings** window contains a **General** section with settings for:

- **Title**
- **Show filename in title**
- **Icon**
- **Menu type**
- **Status bar**

![Settings window](image)

The **Title** is the text at the top of the main window in an application, with the **Icon** shown to the far left of this text. By default, the **Title** is the same as the title of the model used to create the application. Keep the check box **Show filename in title**.
selected if you wish to display the file name of the application to the left of the
Title.

In the Icon list, select an image from the library or add an image (*.png) from
the local file system to the library and use it as an icon. If you add a new image,
it will be added to the image library and thereby embedded into the application.
You can also export an icon by clicking the Export button to the right of the
button Add Image to Library and Use Here.

The Main Window node of the application tree has one child node, named Menu
Bar. Using the Menu type setting, you can change this child node from Menu Bar
to Ribbon.

The Status bar list controls what is shown in the status bar. Select Progress to
display a progress bar when applicable (the default), or None. Note that you can
also create custom progress bars by using methods.

Main Form

The Main Form section contains a reference to the form that the main window
displays. This setting is important when using a form collection because it
determines which form is displayed as the main window when the application is
opened for the first time.

Size

In the Size section, the Initial size setting determines the size of the main window
when the application is first started. There are three options:

• Maximized results in the window being maximized when the application is
  run.

• Use main form’s size uses the size of the main form; See “The Individual Form
  Settings Windows” on page 41. The main form is defined by the Main Form
  section. This option further adds the size required by the main window
  itself, including: the window frame and title bar, main menu, main toolbar,
  and ribbon. This size is computed automatically and depends on whether
  the menu type is Menu bar or Ribbon.

• Manual lets you enter the pixel size for the width and height. In this case,
  nothing is added to the width and height. When using this option, you need
to ensure that there is enough room for the window title, ribbon, and
  menu bar.

For more information on the option Use main form’s size, see “The Form Settings
Window and the Grid” on page 97.
ABOUT DIALOG

The About Dialog section contains settings for customizing parts of the About This Application dialog box, which contains legal information. The Placement option lets you choose between Automatic, File menu, Ribbon, or Lower-right corner. The Lower-right corner option will place a hyperlink to the About This Application dialog box in the lower-right corner of the application user interface. If selected, the check box Show COMSOL information will display COMSOL software version and product information. Any text entered in the Custom text field will be displayed above the legal text in the dialog box. In the Custom text field, words containing http or www will be interpreted as hyperlinks, if possible. For example, http://www.comsol.com or www.comsol.com will be replaced with a hyperlink.

Menu Bar and Toolbar

The Menu Bar node can have Menu child nodes that represent menus at the top level of the Main Window.
For the **Menu Bar** option, you can also add a **Toolbar**. The **Toolbar** node and the **Menu** nodes have the same type of child nodes.

**MENU, ITEM, AND SEPARATOR**

The child nodes of the **Menu** and **Toolbar** nodes can be of type **Menu**, **Item**, **Toggle Item**, or **Separator**, exemplified in the figure below:

A **Menu** node has settings for **Name** and **Title**.
A **Menu** node can have child **Menu** nodes that represent submenus. A **Separator** displays a horizontal line between groups of menus and items, and has no settings.

The **Settings** window for an **Item** node is similar to that of a button and contains a sequence of commands. Just like a button, an item can have associated text, an icon, and a keyboard shortcut. For more information, see “Button” on page 51. In a similar way, the **Settings** window for a **Toggle Item** node is similar to that of a toggle button.

The figure below shows the **Settings** window for an **Item** associated with a method for creating a report.

![Settings window](image-url)
The figure below shows an example of an application with a **File** menu.

When running an application in the COMSOL Desktop environment, a **Close Application** menu item is always present.

The **Settings** window for the **Save As** item is shown in the figure below.

You can enable and disable ribbon, menu, and main toolbar items from methods. For more information, see “Appendix E — Built-in Method Library” on page 285.
**Ribbon**

You can opt to add a **Ribbon** to the **Main Window** instead of a **Menu Bar**. The **Ribbon** node contains the specifications of a ribbon with toolbars placed on one or several tabs. For the **Ribbon** option, a **File** menu is made available directly under the **Main Window** node.

**Ribbon Tab and Ribbon Section**

Child nodes to the **Ribbon** node are of the type **Ribbon Tab**. Child nodes to a **Ribbon Tab** are of the type **Ribbon Section**. Child nodes to a **Ribbon Section** can be of the type **Item**, **Toggle Item**, **Menu**, or **Separator**. **Item** and **Menu** provide the same functionality as described previously for the **Menu Bar** and **Toolbar**. A **Separator** added as a child to a **Ribbon Section** is a vertical line that separates groups of **Items** and **Menus** in the running application. A **Separator** is displayed as a horizontal line in the application tree. The figure below shows an example.
Events

An event is any activity (for example, clicking a button, typing a keyboard shortcut, loading a form, or changing the value of a variable) that signals a need for the application to carry out one or more actions. Each action can be a sequence of commands of the type described earlier, or may also include the execution of methods. The methods themselves may be local methods associated with particular form objects or global methods that can be initiated from anywhere in the application. The global methods are listed in the Methods node of the application tree. The local methods are defined in the Settings windows of the forms or form objects with which they are associated. When a form object has an associated method, it may be opened for editing by performing a Ctrl+Alt+click on the object. If the Ctrl+Alt+click is performed on a form object that has no method, then a new local method, associated with the object, will be created and opened for editing.

The events that initiate these actions may also be global or local. The global events are listed in the Events node of the application tree and include all events that are triggered by changes to the various data entities, such as global parameters or string variables. Global events can also be associated with the startup and shutdown of the application. The local events, like local objects, are defined in the Settings windows of the forms or form objects with which they are associated.

Event nodes trigger whenever the source data changes, regardless of if it is changed from a method, form object, or in any other way. Events associated with form objects only trigger when the user changes the value in the form object.
Events at Startup and Shutdown

Global or local methods can be associated with the events at startup (On startup) and shutdown (About to shutdown) of an application. To access these events, click the Events node in the application tree.

A shutdown event is triggered when:
- The user of an application closes the application window by clicking the Close Application icon in the upper-right corner of the application window
- The Exit Application command is issued by a form object
- A method is run using the command exit()

A method run at a shutdown event can, for example, automatically save critical data or prompt the user to save data. In addition, a method run at a shutdown event may cancel the shutdown by returning a Boolean true value.

Note that a method that is used for initializing graphics, such as Zoom Extents, needs to be run as an On load event for a form and not as a global On startup event.

Global Events

Right-click the Events node and choose Event to add an event to an application. An event listens for a change in a running application. If a change occurs, it runs
a sequence of commands. In the figure below, when the value of the string variable \texttt{SpanWidth} is changed, the method \texttt{setResultsStatus} is run.

Note that since this type of event has global scope and is not associated with a particular form, the full path: /form1/graphics1 needs to be used when referencing graphics objects.

The following two sections describe the options available in the \textbf{Settings} window of an event.
**Source For Data Change Event**

This section presents a filtered view of the tree from the Application Builder window. The nodes represent some sort of data or have children that do. You can extend the list of available data nodes by clicking on the **Switch to Model Builder and Activate Model Data Access** button in the header of the section **Source For Data Change Event**.

For more information, see “Model Data Access in the Method Editor” on page 151.

Note that **Explicit** selections are also allowed as **Source for Data Change Event**. This allows a command sequence or a method to be run when the user clicks a geometry object, domain, face, edge, or point. The figure below shows a dialog.
box for a global event that opens a form panel as a dialog box when the user changes the contents of the **Explicit** selection named **Outlet**.

**Choose Commands to Run**

In the **Settings** window for an **Event**, the section **Choose Commands to Run** is similar to that of a button and allows you to define a sequence of commands. For more information, see “**Button**” on page 51.
Form and Form Object Events

Form and form object events are similar to global events, but are defined for forms or individual form objects. These events have no associated list of commands, but refer directly to one global or local method.

Events Triggered by Data Change

For certain types of form objects, you can specify a method to run when data is changed. This setting is available in the Events section of the form object, as shown in the figure below.

```
Events

<table>
<thead>
<tr>
<th>Events</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>On data change</td>
<td>method1</td>
</tr>
</tbody>
</table>
```

The drop-down list On data change contains None (the default), any available methods under the Methods node of the application tree, and a local method (optional).

The form objects supporting this type of event are:

- Input Field
- Check Box
- Combo Box
- File Import
- Array Input
- Radio Button
- Text
- List Box
- Table
- Slider

Buttons have associated events triggered by a click. Menu, ribbon, and toolbar items have associated events triggered by selecting them. The corresponding action is a command sequence defined in the Settings window of a button object or item. For more information on command sequences, see “Button” on page 51.

Selecting Multiple Form Objects

You can specify an On data change event for multiple form objects simultaneously by using Ctrl+click and then selecting the method to run. In this way, you can, for example, quickly specify that a data change event initiated by any of the selected
form objects should run a method that informs the user that plots and outputs are invalid.

**Events Triggered by Loading or Closing a Form**

Forms can run methods when they are loaded (**On load**) or closed (**On close**).

This type of event is available in the **Settings** window of a form and is typically used when a form is shown as a dialog box, or to activate forms used as panes in a form collection. Note that a method that is used for initializing graphics, such as **Zoom Extents**, needs to be run as an **On load** event for a form and not as a global **On startup** event.

**Using Local Methods**

Events can call local methods that are not displayed in the application tree. For more information on local methods, see “Local Methods” on page 163.
Declarations

The Declarations node in the application tree is used to declare global variables, which are used in addition to the global parameters and variables already defined in the model. Variables defined under the Declarations node are used in form objects and methods. In form objects, they store values to be used by other form objects or methods. Variables that are not passed between form objects and methods, but that are internal to methods, do not need to be declared in the Declarations node. In methods, variables defined under the Declarations node have global scope and can be used directly with their name. For information on how to access global parameters defined in the model tree, see “Accessing a Global Parameter” on page 173.

There are seven different types of declarations:

- Scalar
- Array 1D
- Array 2D
- Choice List
- File
- Unit Set
- Shortcuts

Right-click the Declarations node to access the declaration types or use the ribbon.

Note that Shortcuts are not created from this menu but by clicking the Create Shortcut button next to the Name in the Settings window of a form object, or by using Ctrl+K for a selected form object.

In addition, the first three types of declarations can be of the following data types:

- String
- Boolean
- **Integer**
- **Double**

In addition to right-clicking the **Declarations** node, you can click the **Create New Variable and Use it as Source** button in the **Source** section of many types of form objects.

This will open a dialog box that lets you quickly declare scalar variables.

**Using Declarations as Input Arguments to Commands**

Certain commands used in the commands sequence of, for example, a button can take an input argument. For more information, see “Button” on page 51.
The figure below shows a command sequence that includes a **Plot Temperature** command with an input argument `form1/graphics`.

You can use declarations as input arguments to commands. To use a scalar variable, 1D array, or 2D array as input arguments, you use the corresponding variable name. To access a single element of an array, or a row or column of a 2D array, use indices. For example, to access the first component in a 1D array `my_variable`, you use `my_variable(1)`. A 2D array element can be retrieved as a scalar by using two indices, e.g. `my_matrix(2,3)`. The indices can themselves be other declared variables, e.g. `my_variable(n)`.

For commands requiring a graphics object as an input argument, only string type declarations are allowed with appropriate indices, if necessary. If there is a graphics object named `graphics1` and also a string declaration named `graphics1`, then the contents of the string declaration will be used. An exception is if single quotes are used, such as `‘graphics1’`, in which case the graphics object `graphics1` is used. This rule is also applied to other combinations of commands and input arguments.

**The Name of a Variable**

The **Name** of a variable is a text string without spaces. The string can contain letters, numbers, and underscores. The reserved names `root` and `parent` are not allowed and Java® programming language keywords cannot be used.
Scalar declarations are used to define variables to be used as strings, Booleans, integers, or doubles.

STRING
A scalar string variable is similar to a global parameter or variable in a model, but there is a difference. A parameter or variable in a model has the restriction that its value has to be a valid model expression, while a scalar string variable has no such restrictions. You can use a string variable to represent a double, integer, or Boolean by using conversion functions in a method. For more information, see “Conversion Methods” on page 298. You can also use a string variable as a source in many form objects, such as input fields, combo boxes, card stacks, and list boxes.

The figure below shows the Settings window for the string variables graphics_pane, email_to, and solution_state.

<table>
<thead>
<tr>
<th>Name</th>
<th>Initial Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphics_pane</td>
<td>Temperature</td>
<td>String</td>
</tr>
<tr>
<td>email_to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>solution_state</td>
<td>issolution</td>
<td>String</td>
</tr>
</tbody>
</table>

String declarations, as well as other declarations, can be loaded and saved from or to a file by using the Load from File and Save to File buttons below the List of Variables table.

The Load from File and Save to File buttons are used to load and save from/to the following file formats:

- Text File (.txt)
The drop-down list where these file formats can be selected is shown in the figure below.

To illustrate the use of declared strings, the figure below shows the Settings window of a card stack object where the string variable `viewCard` is used as the source (Active Card Selector).

For more information on using card stacks, see “Card Stack” on page 224.
**BOOLEAN**

You can use a Boolean variable as a source in check boxes, other form objects, and methods. A Boolean variable can have two states: `true` or `false`. The default value is `false`. The figure below shows the declaration of two Boolean variables.

### Example Code

In the example code below, the Boolean variable `bvar` has its value controlled by a check box. If `bvar` is `true`, then plot group 4 (`pg4`) is plotted in `graphics1`. Otherwise, plot group 1 (`pg1`) is plotted.

```java
if (bvar) {
    useGraphics(model.result("pg4"),"graphics1");
} else {
    useGraphics(model.result("pg1"),"graphics1");
}
```
**INTEGER AND DOUBLE**

Integer and double variables are similar to strings, with the additional requirement that the value is an integer or double, respectively.

### Array 1D

The **Array 1D** node declares one or more named arrays of strings, Booleans, integers, or doubles that you can access from form objects and methods. The number of elements in a 1D array is not restricted in any way, and you can, for example, use a 1D array to store a column in a table with a variable number of rows. The **Settings** window contains a single table, where you specify one variable.
array per row. In the figure below, two double arrays are declared, xcoords and ycoords.

The values in the column New element value are assigned to new elements of the array when a row is added to a table form object. Arrays for strings, Booleans, and integers are similar in function to arrays of doubles.

**INITIAL VALUES**

The Initial values can be a 1D array of arbitrary length. To edit the initial values, click the Edit Initial Values button below the List of Variables. This opens a dialog box where the value of each component can be entered. See the figure below for an example of a 1D array of doubles.
ARRAY SYNTAX

An array definition must start and end with curly braces ({} and {}) and each element must be separated with a comma. When you need special characters inside an array element (spaces and commas, for example), surround the element with single quotes ('). The table below shows a few examples of 1D arrays:

<table>
<thead>
<tr>
<th>ARRAY SYNTAX</th>
<th>RESULTING ARRAY</th>
</tr>
</thead>
<tbody>
<tr>
<td>{1, 2, 3}</td>
<td>A 3-element array with the elements 1, 2, and 3</td>
</tr>
<tr>
<td>{}</td>
<td>An empty array</td>
</tr>
<tr>
<td>{'one, two', 'three by four'}</td>
<td>A 2-element array with elements containing special characters</td>
</tr>
<tr>
<td>{{1, 2, 3},{'one, two', 'three by four'}}</td>
<td>A 2-element array containing one 3-element array and one 2-element array</td>
</tr>
</tbody>
</table>

Array 2D

The Array 2D node declares one or more 2D arrays that you can access using form objects and methods. In the figure below, the 2D double array `xycoords` is declared.

INITIAL VALUES

The default (or initial) value can be a 2D array of arbitrary size. To edit the initial values, click the Edit Initial Values button below the List of Variables. This opens a
dialog box where the value of each component can be entered. See the figure below for an example of a 2D array of doubles.

**ARRAY SYNTAX**

The table below shows a few examples of 2D arrays:

<table>
<thead>
<tr>
<th>ARRAY SYNTAX</th>
<th>RESULTING ARRAY</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{}</code></td>
<td>An empty 3D array</td>
</tr>
<tr>
<td><code>{5, 6}, {7, 8}</code></td>
<td>A 2-by-2 matrix of strings</td>
</tr>
<tr>
<td><code>{1, 2, 3}, {4, 5, 6}</code></td>
<td>A 2-by-3 matrix of doubles</td>
</tr>
</tbody>
</table>

For 2D arrays, rows correspond to the first index so that `{{1,2,3},{4,5,6}}` is equivalent to the matrix:

```
1 2 3
4 5 6
```

Assuming that the above 2-by-3 matrix is stored in the 2D array variable `arr`, then the element `arr[1][0]` equals 4.

**Choice List**

The **Choice List** node contains lists that can be used by combo boxes, radio buttons, or list boxes. The **Settings** window for a choice list contains a **Label**, a **Name**, and a table with a **Value** column and a **Display name** column. Enter the
property value (Value) in the first column and the corresponding text to display to the user (for example, in a combo box list) in the second column (Display name). The Value is always interpreted as a string. In the example below, mat1 will become the string “mat1” when returned from the combo box.

As an alternative to creating a choice list by right-clicking the Declarations node, you can click the Add New Choice List button in the Settings window for form objects that use such a list, as shown in the figure below.

**Activation Condition**

You can right-click the Choice List node to add an Activation Condition subnode. Use an activation condition to switch between two or more choice lists contingent on the value of a variable. For an example of using choice lists with activation conditions, see “Using a Combo Box to Change Material” on page 196.
File declarations are primarily used for file import in method code when using the built-in method `importFile`. For more information on the method `importFile` and other methods for file handling, see “File Methods” on page 286. However, an entry under the `File` declaration node can also be used by a `File Import` object. The figure below shows the Settings window of a file declaration.

The file chosen by the user can be referenced in a form object or method using the syntax `upload://file1, upload://file2`, etc. The file name handle (`file1`, `file2`, etc.) can then be used to reference an actual file name picked by the user at run time.

For more information on file declarations and file handling, see “Appendix C — File Handling and File Scheme Syntax” on page 263.
The **Unit Set** node contains lists that can be used by combo boxes, radio buttons, or list boxes for the purpose of changing units. The **Settings** window for a unit set contains two sections: **Unit Groups** and **Unit Lists**.

<table>
<thead>
<tr>
<th><strong>Unit Groups</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Value</strong></td>
</tr>
<tr>
<td>SI</td>
</tr>
<tr>
<td>imperial</td>
</tr>
</tbody>
</table>

Each row in the **Unit Groups** table is a unit group that represents a collection of units with a particular meaning in the context of the application user interface. Each column represents a group of units labeled by a **Value** and a **Display name**.

Each row in the **Unit Lists** table is a unit list with columns containing units with the same dimension; for example: mm, cm, dm, m, km. The headings of the **Unit Lists** table are **Name** and the **Display names** are defined in the **Unit Groups** section. A unit list specifies the possible units that a form object that references the **Unit Set** can switch between when running the application.

The figure above demonstrates the use of a **Unit Set** for an application that allows for switching between metric and imperial units. In this example, two unit groups are defined: SI and Imperial. The **Label** of the **Unit Set** has been changed to UNIT SYSTEM.

The **Value** column contains string values that represent the current choice of unit group. These string values can be manipulated from methods. The **Display name**
column is the string displayed in the user interface. The Initial value list contains the default unit group (SI in the example above).

In the example above, the Unit Lists table has three columns: Name, SI, and Imperial. The SI and Imperial columns are created dynamically based on the groups in the Unit Groups section. Each row in the table corresponds to a physical quantity such as, in this example, length and potential. Each column in the table corresponds to the allowed units of length and units of potential, respectively. The figure below shows an example application where a combo box form object is used to choose between the SI and Imperial unit groups.
The figure below shows the Settings window of a combo box using the Unit Set of the above example as the Source.

In this way, a Unit Set can be used instead of a Choice List to create a combo box for unit selection. Instead of a combo box, you can use a list box or a radio button object in a similar way.
The two figures below show the corresponding **Settings** windows for the two input fields for **Length** and **Applied voltage**.

The **Unit dimension check** is set to **Append unit from unit set**. The **Unit set** is set to **Unit System (unitset1)** (the user-defined label for the **Unit Set** declaration used in this example). The **Unit list** is set to **length** and **potential**, respectively. When using **Append unit from unit set**, the **Numerical validation** section (under **Data Validation**) refers to the **Initial value** of a **Unit Set**; in this case, **cm** and **mV**, respectively. The **Minimum** and **Maximum** values are scaled automatically when the application is run and the unit is changed by the user of the application. For more information on the settings for an input field object, see “Input Field” on page 77.
The figures below illustrate the use of two Unit Set declarations for separately setting the unit for length and potential, respectively.

The figures below show the corresponding Settings window for the Unit Set declarations.

Note that, in this example, by using three Unit Set declarations, you can have individual length unit settings for the Length and Width input fields. The figure
below shows such an example, where three combo boxes have been used to replace the unit labels and each combo box uses a separate Unit Set declaration as its source.

When more flexibility is required, you can combine the use of a Choice List and a Unit Set. For example, for a combo box, you can use the Unit Set as the Selected source (string) and select a Choice List that is not a Unit Set.

**Shortcuts**

Form objects and other user interface comments are referenced in methods by using a certain syntax. For example, using the default naming scheme form3/button5 refers to a button with the name button5 in form3 and form2/graphics3 refers to a graphics object with the name graphics3 in form2. You can also change the default names of forms and form objects. For example, if form1 is your main form, then you can change its name to main.

To simplify referencing form objects as well as menu, ribbon, and toolbar items by name, you can create shortcuts with a custom name. In the Settings window of an object or item, click the button to the right of the Name field and type a name of your choice.
To create or edit a shortcut, you can also use the keyboard shortcut Ctrl+K. All shortcuts that you create are made available in a **Shortcuts** node under **Declarations** in the application tree.

In the **Settings** window for **Shortcuts** below, two shortcuts, `plot_temp` and `temp_vis`, have been created for a button and a graphics object, respectively.

<table>
<thead>
<tr>
<th>Name</th>
<th>Target</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_temp</td>
<td>form1/button1</td>
<td>Shortcut to Button</td>
</tr>
<tr>
<td>temp_vis</td>
<td>form3/graphics3</td>
<td>Shortcut to Graphics</td>
</tr>
</tbody>
</table>

The shortcuts can be referenced in other form objects or in code in the Method editor. The example below shows a shortcut, `temp_vis`, used as an input argument to a temperature plot.

Shortcuts are automatically updated when objects are renamed, moved, copied, and duplicated. They are available in application methods as read-only Java® variables, just like string, int, double, and Boolean declarations. Using shortcuts is recommended because it avoids the need to adjust method editor code when the structure of the application user interface changes.
The Method Editor

Use the Method editor to write code for actions not included among the standard run commands of the model tree nodes in the Model Builder. The methods may, for example, execute loops, process inputs and outputs, and send messages and alerts to the user of the application.

The Java® programming language is used to write COMSOL methods, which means that all Java® syntax and Java® libraries can be used. In addition to the Java® libraries, the Application Builder has its own built-in library for building applications and modifying the model object. The model object is the data structure that stores the state of the underlying COMSOL Multiphysics model that is embedded in the application. More information on these built-in methods can be found in “Appendix E — Built-in Method Library” on page 285 and in the Application Programming Guide.

The contents of the application tree in the Application Builder is accessed through the application object, which is an important part of the model object. You can record and write code using the Method editor that directly access and change user interface aspects of the running application, such as button texts, icons, colors, and fonts.

Methods can be global or local. Global methods are displayed in the application tree and are accessible from all methods and form objects. A local method is associated with a form object or event and can be opened from the corresponding Settings window. For more information about local methods, see “Local Methods” on page 163.

A number of tools and resources are available to help you create code for methods. These are covered in the following sections, and will make you more productive, for example, by allowing you to copy-paste or autogenerate blocks of code.

Converting a Command Sequence to a Method

In the Form editor, click the Convert to New Method button displayed in the Settings window below an existing command sequence. The command sequence is automatically replaced by an equivalent method.

Consider a case where you have created a compute button and you want to be alerted by a sound when the computation has finished. Now, we will see how this could be done using the Method editor.
You will also learn how to do this without using the Method editor later in this section. The figure below shows the **Settings** window of the **Compute** button.

Click the **Convert to New Method** button below the command sequence.
The command sequence in this example is replaced by a method, method3. Click the **Go to Method** button. The Method editor opens with the tab for method3 active.

In the Method editor, add a call to the built-in method `playSound` to play the sound file `success.wav`, available in the COMSOL sound library, by using the syntax shown in the figure below.

The newly added line is indicated by the green bar shown to the left.
Note that in the example above, you do not have to use the Method editor. In the command sequence, select the file `success.wav` under Libraries > Sounds and click the Run command button under the tree, as shown in the figure below.

However, there are many built-in methods that do not have corresponding command sequence nodes. For more information, see “Appendix E — Built-in Method Library” on page 285.
**Form Object with Associated Method**

A form object that has an associated method is indicated with a special icon, as shown in the figure below. In this example, both the check box called **Find prong length** and the **Compute** button have associated methods.

Performing Ctrl+Alt+Click on the form object opens the method in the Method editor. If there is no method associated with the form object, a new local method associated with the form object will be created and opened in the Method editor. If the associated method has a compile error, then this is shown with a different icon, as shown in the figure below.
Language Elements Window

The **Language Elements** window in the Method editor shows a list of some language constructs. Double-click or right-click one of the items in the list to insert template code into the selected method.

![Language Elements Window](image)

See also “Language Element Examples” on page 170.

Editor Tools in the Method Editor

To display the **Editor Tools** window, click the corresponding button in the **Main** group in the **Method** tab.

![Editor Tools](image)

When using the **Editor Tools** window in the Method editor, you can right-click a node in the editor tree to generate code associated with that node. Depending on the node, up to eight different options are available:

- Get
- Set
- Set All
- Create
- Run
- Enable
- Disable
- Edit Node

Selecting one of the first seven options will add the corresponding code to the currently selected method. The **Edit Node** option brings you to the **Settings** window for the model tree node.
The figure below shows an example of a node with six options.

When a node is selected, the toolbar below the editor tree shows the available options for generating code.

The Editor Tools window is also an important tool when working with the Form editor. For more information, see “Editor Tools in the Form Editor” on page 49.
**KEYBOARD SHORTCUTS**

Consider a method with a line of code that refers to a model object in the following way:

```java
model.result("pg3").feature("surf1").create("hght1", "Height");
```

If you position the mouse pointer in "surf1" and press F11 on the keyboard, right-click and select **Go to Node**, or click **Go to Node** in the ribbon, then the corresponding Surface plot note is highlighted in the Editor Tools window.

Click **Edit Node** to open its **Settings** window. For more information on keyboard shortcuts, see “Appendix D — Keyboard Shortcuts” on page 283.

---

**Model Data Access in the Method Editor**

To access individual properties of a model tree node, click the **Model Data Access** button in the **Application** section of the Model Builder ribbon tab.

Alternatively, for certain form objects, you can click the **Model Data Access** button in the header of the **Source** section of the **Settings** window. See also “Model Data Access in the Form Editor” on page 88.

**Model Data Access** needs to be enabled this way because a model typically contains hundreds or even thousands of properties that could be accessed, and the list would be too long to be practical.

When you click a model tree node, such as the **Heat Flux** node in the figure below, check boxes appear next to the individual properties. This example is based on the busbar tutorial model described in *Introduction to COMSOL Multiphysics*. 
In the figure below, the check boxes for **Heat transfer coefficient** and **External temperature** are selected:
If you switch to the **Editor Tools** window, you will see additional nodes appear under the **Heat Flux** node. Right-click and use **Get** or **Set** to generate code in an active method window, as shown in the figure below.

In the example above, **Get** and **Set** for the **Heat transfer coefficient** and the **External temperature** properties will generate the following code:

```plaintext
model.physics("ht").feature("hf1").getString("h");
model.physics("ht").feature("hf1").getString("Text");
model.physics("ht").feature("hf1").set("h", "htc");
model.physics("ht").feature("hf1").set("Text", '293.15[K]' );
```

**Recording Code**

Click the **Record Code** button in the **Code** section of the Method editor ribbon to record a sequence of operations that you perform using the model tree, as shown in the figure below.
Certain operations in the application tree can also be recorded, including methods used to modify the user interface while the application is running such as changing the color of a text label.

To record a new method, click the **Record a New Method** button in the **Main** section of the Method editor ribbon.

While recording code, the COMSOL Desktop windows are surrounded by a red frame:
To stop recording code, click one of the Stop Recording buttons in the ribbon of either the Model Builder or the Application Builder.

The previous section on Model Data Access explained how to set the values of the Heat transfer coefficient and the External temperature properties of the busbar tutorial model. To generate similar code using Record Code, follow these steps:

- Create a simple application based on the busbar model (MPH file).
- In the Model Builder window, click Record a New Method, or with the Method editor open, click Record Code.
- Change the value of the Heat transfer coefficient to 5.
- Change the value of the External temperature to 300[K].
- Click Stop Recording.
- If it is not already open, open the method with the recorded code.

The resulting code is listed below:

```c++
with(model.physics("ht").feature("hf1"));
set("h", "5");
set("Text", "300[K]");
```
In this case, the automatic recording contains a `with()` statement in order to make the code more compact. For more information on the use of `with()`, see “The With Statement” on page 172.

To generate code corresponding to changes to the application object, use **Record Code** or **Record a New Method**, then go to the Form editor and, for example, change the appearance of a form object. The following code corresponds to changing the color of a text label from the default `Inherit to Blue`:

```javascript
with(app.form("form1").formObject("textlabel1"));
  set("foreground", "blue");
endwith();
```

For more information on modifying the model object and the application object, see the *Application Programming Guide*.

Use the tools for recording code to quickly learn how to interact with the model object or the application object. The autogenerated code shows you the names of properties, parameters, and variables. Use strings and string-number conversions to assign new parameter values in model properties. By using **Model Data Access** while recording, you can, for example, extract a parameter value using `get`, process its value in a method, and set it back into the model object using `set`. For more information on **Model Data Access**, see “Model Data Access in the Method Editor” on page 151.

### Checking Syntax

Click **Check Syntax** in the ribbon to see messages in the **Errors and Warnings** window related to syntax errors or unused variables.
In addition to messages in the **Errors and Warnings** window, syntax errors are indicated with a wavy red underline, as shown in the figure below.

**Find and Replace**

Click **Find** in the Quick Access Toolbar to open a dialog box used to find and replace strings in methods, as shown in the figure below.

The Quick Access Toolbar is located above the ribbon to the left, in the COMSOL Desktop user interface.
The **All** tab is used to find strings and variables in both the Model Builder and the Application Builder.

**Model Expressions Window**

The **Model Expressions** window in the Method editor shows a list of predefined expressions used as input and output arguments. Double-click or right-click one of the items in the list to insert an expression:

![Model Expressions Window](image)
Extracting Variables

If you look at the example below, you will notice that each line of code has a repeating prefix.

Readers familiar with object-oriented programming will recognize such a prefix as the name of an object instance. The Extract Variable button simplifies code by replacing these instances with a variable name.

In the example above, the mouse pointer has been positioned at the first occurrence of feature. Click the Extract Variable button to transform the source code into what is shown in the figure below.

The code starting with the prefix feature has been replaced with the variable mslc1. When you click the Extract Variable button, an Extract Variable dialog box opens where you can enter a suitable variable name in the Name field.
Syntax Highlighting, Code Folding, and Indentation

Different language elements in the code are displayed using different styles. Refer to the figure below for an example:

```java
with(model.result("p2")) {
    set("looplevel", new String[]{"?"}); // 7th frequency
    endWin();
    useGraphics(model.result("p2"), "graphics1");
    zoomExit("graphics1");
    if (customProgress) {
        setProgressForm("progressform/progress1", 100);
    }
    else {
        setProgress(100);
    }
    play Löud();

    if (customProgress) {
        closeDialog("progressform");
    }
    else {
        closeProgress();
    }
}
```

This example includes five styles:

- Keywords, such as `if`, `else`, `for`, `while`, `double`, and `int` are displayed in bold blue font
- Built-in methods are displayed in italic blue font
- Strings are displayed in red font
- Comments are displayed in green font
- The remainder of the code is displayed in black font

You can customize the syntax highlighting theme in the Preferences dialog box. See the next section “Method Editor Preferences”.

You can expand and collapse parts of the code corresponding to code blocks that are part of `for`, `while`, `if`, and `else` statements. This feature can be disabled, as described in the next section “Method Editor Preferences”.

When writing code, press the Tab key on your keyboard to automatically indent a line of code and to insert white spaces where needed. Indentation and whitespace formatting also happen automatically when the keyboard focus leaves the Method editor. You can disable this behavior in Preferences in the Method section by clearing the check box Indent and format automatically.

160 |
THE NAME OF A METHOD

The Name of a method is a text string without spaces. The string can contain letters, numbers, and underscores. The reserved names root and parent are not allowed and Java® programming language keywords cannot be used.

Method Editor Preferences

To access the Preferences for the methods, choose File > Preferences and select the Methods section.

By default, the Method editor only shows the most relevant code. To see all code in a method, select the View all code check box.

The check box Close brackets automatically controls whether the Method editor should automatically add closing brackets, such as curly brackets {}, brackets [], and parentheses ().

The check box Generate compact code using ’with’ statements controls the utilization of with statements in automatically generated code. For more information, see “The With Statement” on page 172.

If the check box Enable code folding is selected, you can expand and collapse parts of the code corresponding to code blocks associated with for, while, if, and else statements.

Selecting the check box Indent and format automatically will ensure that code is consistently indented and formatted.
Under **Syntax highlighting**, the **Theme** list contains two predefined themes, **Modern** (the default) and **Classic**. Choose **User defined** to define a syntax highlighting mode where the colors can be assigned to individual language elements.

**Ctrl+Space and Tab for Code Completion**

While typing code in the Method editor, the Application Builder can provide suggestions for code completions. The list of possible completions are shown in a separate completion list that opens while typing. In some situations, detailed information appears in a separate window when an entry is selected in the list. Code completion can always be requested with the keyboard shortcut Ctrl+Space. When accessing parts of the model object, you will get a list of possible completions, as shown in the figure below:

Select a completion by using the arrow keys to choose an entry in the list and press the Tab or Enter key to confirm the selection.

If the list is long, you can filter by typing the first few characters of the completion you are looking for.

For example, if you enter the first few characters of a variable or method name and press Ctrl+Space, the possible completions are shown:

In the example above, only variables that match the string `iv` are shown. This example shows that variables local to the method also appear in the completion suggestions.
You can also use Ctrl+Space to learn about the syntax for the built-in methods that are not directly related to the model object. Type the name of the command and use Ctrl+Space to open a window with information on the various calling signatures available.

For a list of available built-in methods, you can use the Language Elements window described on page 148 or see “Appendix E — Built-in Method Library” on page 285.

The keyboard shortcut Ctrl+Space can also be used in the Model Builder. For example, when typing in an Expression field in Results, use Ctrl+Space to see matching variables, as shown in the figure below.

**Local Methods**

You can add local methods to buttons, menu items, and events. Local methods do not have nodes displayed under the Methods node in the application tree. In the
method window for a local method, its tab displays the path to its associated user interface component, as shown in the figure below for the case of a check box object.

In the Form editor, you can right-click a form object and select **Create Local Method** from a menu, as shown in the figure below.
LOCAL METHODS FOR BUTTONS, MENU ITEMS, AND GLOBAL EVENTS

For buttons, ribbons, menus, toolbar items, and global events, you can add a local method by clicking the **Create Local Method** toolbar button under the sequence of commands, as shown in the figure below.

The function of this button is similar to the **Convert to New Method** button, described in the section “Creating a New Method” on page 15. The only difference is that it creates a local method not visible in the global method list in the application tree. It also opens the new method in the Method editor after creating it. Ctrl+Alt+Click can be used as a shortcut for creating the local method. Clicking the button **Go to Method** will open the local method. The figure below shows a call to a local method associated with a button.
To avoid any risk of corrupting code in a local method, you are unable to use Convert to New Method when there is a local method present in the command sequence.

**Local Methods for Form and Form Object Events**

To add a local method for a form or form object event, click the Create Local Method button in the Events section of the Settings window. The selected On data change method changes from None to Local method, as shown in the figure below, and the Method editor is opened.

![Setting up local methods](image)

To open an existing local method in the Method editor, click the Go to Source button. Click the Remove Local Method button to delete the local method.

As an alternative to Ctrl+Alt+Click, you can right-click a form object and select Edit Local Method from its context menu.

![Context menu options](image)

For more information, see “Events” on page 117.

**Methods with Input and Output Arguments**

A method is allowed to have several input arguments and one output argument. You define input and output arguments in the Settings window of an active method window. If the Settings window is not visible, click Settings in the Method tab of the ribbon. The figure below shows a method with two input arguments, var and coords, and one output, coordsout. The method adds random values to
the array, \texttt{coords}. The degree of randomness is controlled by the input variable \texttt{var}. The new values are stored in the array \texttt{coordsout}.

When you call another method from a method, Ctrl+Alt+Double-Click opens the window for that method. A method is allowed to call itself for the purpose of recursion.
Debugging

For debugging purposes, click in the gray column to the left of the code line numbers to set breakpoints, as shown in the figure below.

In the ribbon, the **Debug** group contains the tools available for debugging methods. When you run the application, the method will stop at the breakpoints. Click the **Step** button to go to the next line in the method. The figure above shows a method currently stopped at the line highlighted in yellow.

Click **Continue** to run the method up until the next breakpoint. Click **Stop** to stop running the method. Click **Step Into** to step into the next method, if possible. Use **Remove All** to remove all break points. Instead of removing, you can disable all
break points by clicking **Disable All**. Click the **Debug Log** to display debugging messages in a separate **Debug Log** window, as shown in the figure below.

Use the `debugLog` command to display the value of variables in the **Debug Log** window. The code below illustrates using the `debugLog` command to display the values of strings and components of a 1D double array.

```java
int len=xcoords.length;
if (selected==0) {
  for (int i = 0; i < len; i++) {
    double divid=double(i)/len;
    xcoords[i] = Math.cos(2.0*Math.PI*divid);
    ycoords[i] = Math.sin(2.0*Math.PI*divid);
    debugLog("x:");
    debugLog(xcoords[i]);
    debugLog("y:");
    debugLog(ycoords[i]);
    debugLog("selected is 0");
  }
}
```
For more information on built-in methods for debugging, see “Debug Method” on page 294.

**Stopping a Method**

You can stop the execution of a method while testing an application by using the keyboard shortcut Ctrl+Pause. A dialog box appears, as shown below.

![Error dialog box showing Method stopped.]

**The Model Object**

The model object provides a large number of methods, including methods for setting up and running sequences of operations. The Convert to Method, Record Code, Editor Tools, and Language Elements utilities of the Method editor produce statements using such model object methods. For more information and example code related to the model object and its methods, see “Appendix C—Language Elements and Reserved Names” in the book *Introduction to COMSOL Multiphysics*, the Application Programming Guide, as well as the Programming Reference Manual.

**Language Element Examples**

The Java® programming language is used to write COMSOL methods, which means that Java® statements and syntax in general can be used. For more information, see the Application Programming Guide and the Programming Reference Manual.
**Unary and Binary Operators in the Model Object**
The table below describes the unary and binary operators that can be used when accessing a model object, such as when defining material properties and boundary conditions, and in results, expressions used for postprocessing and visualization.

<table>
<thead>
<tr>
<th>PRECEDENCE LEVEL</th>
<th>SYMBOL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( ) {}</td>
<td>grouping, lists, scope</td>
</tr>
<tr>
<td>2</td>
<td>^</td>
<td>power</td>
</tr>
<tr>
<td>3</td>
<td>! - +</td>
<td>unary: logical not, minus, plus</td>
</tr>
<tr>
<td>4</td>
<td>[ ]</td>
<td>unit</td>

</tbody>
</table>

**Unary and Binary Operators in Methods (Java® Syntax)**
The table below describes the most important unary and binary operators used in Java® code in methods.

<table>
<thead>
<tr>
<th>PRECEDENCE LEVEL</th>
<th>SYMBOL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>++ --</td>
<td>unary: postfix addition and subtraction</td>
</tr>

</tr>
<tr>
<td>10</td>
<td>?:</td>
<td>conditional ternary</td>
</tr>
</tbody>
</table>
Variables defined in the Declarations node are available as global variables in a method and need no further declarations.

**BUILT-IN ELEMENTARY MATH FUNCTIONS**

Elementary math functions used in methods rely on the Java® math library. Some examples:

- `Math.sin(double)`
- `Math.cos(double)`
- `Math.random()`
- `Math.PI`

**THE IF STATEMENT**

```java
if(a<b) {
    alert(toString(a));
} else {
    alert(toString(b));
}
```

**THE FOR STATEMENT**

```java
// Iterate i from 1 to N:
int N=10;
for (int i = 1; i <= N; i++) {
    // Do something
}
```

**THE WHILE STATEMENT**

```java
double t=0,h=0.1,tend=10;
while(t<tend) {
    //do something with t
    t=t+h;
}
```

**THE WITH STATEMENT**

```java
// Set the global parameter L to a fixed value
with(model.param());
set("L", '10[cm]");
```
The code above is equivalent to:
```java
model.param().set("L", "10[cm]");
```

**ACCESSING A GLOBAL PARAMETER**

You would typically use the **Editor Tools** window for generating code for setting the value of a global parameter. While in the Method editor, right-click the parameter and select **Set**.

To set the value of the global parameter \( L \) to 10 cm:
```java
model.param().set("L", "10[cm]");
```

To get the global parameter \( L \) and store it in a double variable \( \text{Length} \):
```java
double \text{Length}=model.param().evaluate("L");
```

The evaluation is in this case with respect to the base **Unit System** defined in the model tree root node.

To return the unit of the parameter \( L \), if any, use:
```java
String \text{Lunit}=model.param().evaluateUnit("L");
```

To write the value of a double to a global parameter, you need to convert it to a string. The reason is that global parameters are model expressions and may contain units.

Multiply the value of the variable \( \text{Length} \) with 2 and write the result to the parameter \( L \) including the unit of cm.
```java
\text{Length}=2*\text{Length};
model.param().set("L", toString(\text{Length})+"[cm]");
```

To return the value of a parameter in a different unit than the base Unit System, use:
```java
double \text{Length\_real} = model.param().evaluate("L","cm");
```

If the parameter is complex valued, the real and imaginary part can be returned as a double vector of length 2:
```java
double[] \text{realImag} = model.param().evaluateComplex("Ex","V/m");
```

**COMPARING STRINGS**

Comparing string values in Java® has to be done with `.equals()` and not with the `==` operator. This is due to the fact that the `==` operator compares whether the strings are the same objects and does not consider their values. The below code demonstrates string comparisons:
```java
boolean \text{streq}=false;
String a="string A";
String b="string B";
```
streq=a.equals(b);
// In this case streq==false

streq=(a==b);
// In this case streq==false

b="string A";
streq=a.equals(b);
// In this case streq==true

**Alerts and Messages**

The methods `alert`, `confirm`, and `request` display a dialog box with a text string and optional user input. The following example uses `confirm` to ask the user if a direct or an iterative solver should be used in an application. Based on the answer, the `alert` function is then used to show the estimated memory requirement for the selected solver type in a message dialog box:

```java
String answer = confirm("Which solver do you want to use?", "Solver Selection","Direct", "Iterative");
if(answer.equals("Direct")) {
    alert("Using the direct solver will require about 4GB of memory when solving.");
} else {
    alert("Using the iterative solver will require about 2GB of memory when solving.");
}
```
Libraries

In the application tree, the Libraries node contains images, sounds, and files to be embedded in an MPH file so that you do not have to distribute them along with the application. In addition, the Libraries node may contain Java® utility class nodes and nodes for external Java® and C libraries.

The embedded files can, for example, be referenced in form objects or in methods by using the syntax `embedded:///file1`, `embedded:///file2`, and so on. For example, to reference the image file `compute.png`, use the syntax `embedded:///compute.png`.

Note that you are not required to have the file extension as part of the file name; instead, arbitrary names can be used. To minimize the size of your MPH file, delete unused images, sounds, or other files.

To manage files loaded by the user of an application at run time, you have several options, including using File declarations and File Import form objects. For more information on files to be loaded at run time, see “File” on page 135, “File Import” on page 228, and “Appendix C — File Handling and File Scheme Syntax” on page 263.

Images

The Images library contains a number of preloaded sample images in the PNG file format. If you wish to embed other image files, click the Add File to Library button below the List of Images. A large selection of images is available in the COMSOL installation folder in the location data/images. Images are used as icons and can
be referenced in image form objects or in methods. For images used as icons, two sizes are available: 16-by-16 pixels (small) and 32-by-32 pixels (large).

Supported image formats are JPG, GIF, BMP, and PNG.

To preview an image, click the name of the image in the **List of Images**. The image is displayed in the **Preview** section, as shown in the figure below.
To export a selected image, click the Export Selected Image File button to the right of the Preview button.

**Sounds**

The Sounds library contains a few preloaded sounds in the WAV file format. If you wish to embed other sound files, click the Add File to Library button below the List of Sounds. A larger selection of sounds is available in the COMSOL installation folder in the location data/sounds.

To play a sound, click the name of the sound and then click the Preview button below the List of Sounds.

Click the Export Selected Sound File button to the right of the Preview button to export a selected sound.

To play a sound in an application, add a command in the Settings window of a button, ribbon, menu, or toolbar item. In the Choose Commands to Run section,
select the sound and click the Run button below the tree. This adds a Play command to the command sequence, as shown in the figure below.

In methods, you can play sounds using the built-in method, `playSound`, such as:

```java
playSound("success.wav");
```
Files

The Files library is empty by default. Click the Add File to Library button to embed files of any type in your application.

Click the Export Selected File button to the right of the Add File to Library button to export a selected file.

The embedded files can be referenced in a method by using the syntax embedded:///data1.txt, embedded:///data2.txt, and so on. For more information, see “File” on page 135, “Appendix C — File Handling and File Scheme Syntax” on page 263, and “File Methods” on page 286.
Appendix A — Form Objects

This appendix provides information about forms and form objects and expands upon the section “The Form Editor” on page 40. The items followed by a * in the following list have already been described in detail in that section. The remaining items are discussed in this appendix.

List of All Form Objects

- Input
  - Input Field*
  - Button*
  - Toggle Button
  - Check Box
  - Combo Box
- Labels
  - Text Label*
  - Unit*
  - Equation
  - Line
- Display
  - Data Display*
  - Graphics*
  - Web Page
  - Image
  - Video
  - Progress Bar
  - Log
  - Message Log
  - Results Table
• Subforms
  - Form
  - Form Collection
  - Card Stack
• Composite
  - File Import
  - Information Card Stack
  - Array Input
  - Radio Button
  - Selection Input
• Miscellaneous
  - Text
  - List Box
  - Table
  - Slider
  - Hyperlink
  - Toolbar
  - Spacer

**Toggle Button**

A **Toggle Button** object is a button with two states: selected and deselected, as shown in the figure below.

The information in this section is also applicable to **Menu Toggle Item** and **Ribbon Toggle Item**.

**Using a Toggle Button to Enable and Disable a Heat Source**

The two states of a toggle button are stored by linking it to a Boolean variable. The figure below shows the **Settings** window of a button that enables and disables
a heat source depending on its state. The Boolean variable `heat_source` is selected in the **Source** section.

Enabled corresponds to the Boolean variable `heat_source` being equal to `true`, which in turn corresponds to the toggle button being selected. Disabled corresponds to the Boolean variable `heat_source` being equal to `false`, which in turn corresponds to the toggle button being deselected.
Below the Source section is the Choose Commands to Run section, with a choice for Action that represents two different commands for Select and Deselect. The figure below shows the Settings window for Deselect with a command Disable Heat Source.
The next figure shows the command sequence for Select with a command Enable Heat Source.

A toggle button is similar to a check box in that it is linked to a Boolean variable. For a toggle button, you define the action by using a command sequence, whereas for a check box, you define the action by using an event. This is described in the next section.

**Check Box**

A **Check Box** has two values: on for selected and off for cleared. The state of a check box is stored in a Boolean variable in the **Declarations** node.
**Using a Check Box to Control Visualization**

The figure below is from an application where a deformation plot is disabled or enabled, depending on whether the check box is selected.

The screenshot on the left shows the running application. The screenshot on the right shows the corresponding form objects in grid layout mode.

In the example below, the state of the check box is stored in a Boolean variable `deformation`, whose *Settings* window is shown in the figure below.
The figure below shows the Settings window for the check box.

You associate a check box with a declared Boolean variable by selecting it from the tree in the Source section and clicking Use as Source.

The text label for a check box gets its name, by default, from the Description field of the Boolean variable with which it is associated.

The initial value of the variable deformation is overwritten by the Value for selected (on) or the Value for cleared (off) and does not need to be edited. When used in methods, the values on and off are aliases for true and false, respectively. These values can be used as Booleans in if statements, for example.

The code statements below come from a local method that is run for an On data change event when the value of the Boolean variable deformation changes.

```java
model.result("pg1").feature("surf1").feature("def").active(deformation);
useGraphics(model.result("pg1"), "graphics1");
```
USING A CHECK BOX TO ENABLE AND DISABLE FORM OBJECTS

The figure below shows a part of an application where certain input fields are disabled or enabled, depending on if the check box is selected.

The figure below shows the Settings window for a check box associated with a Boolean variable findlength used to store the state of the check box.

The code statements below come from a local method that is run for an On data change event when the value of the Boolean variable findlength changes.

```java
setFormObjectEditable("main/inputfield1", !findlength);
setFormObjectEditable("main/inputfield5", findlength);
setFormObjectEnabled("main/inputfield5", findlength);
setFormObjectEditable("main/inputfield6", findlength);
setFormObjectEnabled("main/inputfield6", findlength);
solution_state = "inputchanged";
```
**Combo Box**

A **Combo Box** can serve as either a combination of a drop-down list box and an editable text field or as a drop-down list box without the capability of editing.

**Using a Combo Box to Change Parameters in Results**

To illustrate the use of a combo box, consider an application where the user selects one of six different mode shapes to be visualized in a structural vibration analysis. This example uses a Solid Mechanics physics interface with an Eigenfrequency study and is applicable to any such analysis.

These six mode shapes correspond to six different eigenfrequencies that the user selects from a combo box:

In this example, the combo box is used to control the value of a string variable `mode`. The figure below shows the **Settings** window for this variable.
Selecting the Source

The figure below shows the Settings window for this combo box.

In the Source section, you select a scalar variable that should have its value controlled by the combo box and click Use as Source. In the Initial values list of the Settings window of the combo box, choose a method to define a default value for the combo box. The options are First allowed value (the default) and Custom default. For the Custom default option, enter a default value in the associated field. The default value that you enter must exist among the allowed values.

Choice List

The vibrational modes 1–6 correspond to trivial rigid body modes and are not of interest in this application, hence the first mode of interest is 7. A choice list allows you to hide the actual mode values in the model from the user by only displaying the strings in the Display name column; the first nonrigid body modes are named Fundamental tone, Overtone 1, Overtone 2, etc.
In the section for **Choice List**, you can add choice lists that contribute allowed values to the combo box. The **Choice List** declaration associated with this example is shown in the figure below.

The string variable `mode` is allowed to have one of these six values: 7, 8, 9, 10, 11, or 12. The text strings in the **Display name** column are shown in the combo box.

In the **Settings** window of the combo box, you can select the **Allow other values** check box to get a combo box where you can type arbitrary values. Such combo boxes can accept any value and are not restricted to the values defined by the choice lists. In this example, however, only six predefined values are allowed.

For more information on choice lists, see “Choice List” on page 133.

**Events**

In the **Events** section, specify a method to run when the value of the combo box, and thereby the string variable used as the source, is changed by the user. In the present case, the value of the variable `mode` is changed, and a local method is run, as shown below.

```java
with(model.result("pg1"));
set("looplevel", new String[]{mode});
endwith();
model.result("pg1").run();
```
This code links the value of the string mode to the Eigenfrequency setting in the Plot Group pg1. In this case, the string svar takes the values ‘7’, ‘8’, ‘9’, ‘10’, ‘11’, or ‘12’.

The code above can be generated automatically by using the recording facilities of the Method editor:

- Go to the Model Builder and click **Record a New Method**.
- By default, when using an Eigenfrequency study for a structural mechanical analysis, a **Mode Shape** plot group is created. In this plot group, change the **Eigenfrequency** from mode 7 to mode 8. In the figure below, this corresponds to changing from 440 Hz to 632.89 Hz in the **Settings** window for the **Mode Shape** plot group.

- Click **Stop Recording**.

The resulting code is shown below.

```java
with(model.result("pg1"));
set("looplevel", new String[]{"8"});
endwith();
model.result("pg1").run();
```

Now change the string "8" with the variable mode to end up with the code listing above. This will be stored in a method, say, `method1`. To create the local method
associated with the combo box, copy the code from method1. Then, delete method1.

Using Model Data Access
A quicker, but less general way, of using a combo box is to use Model Data Access in combination with Editor Tools. For the example used in this section, you start by enabling Model Data Access and, in the Settings window of the Mode Shape plot group, select the Eigenfrequency, as shown in the figure below.

In the Editor Tools window, the Eigenfrequency parameter is visible as Loop Level. To create a combo box, right-click Loop Level and select Input.

The generic name Loop Level is used for a solution parameter. If a solution has two or more parameters, then there are two or more loop levels to choose from.
The figure below shows the Settings window of the corresponding combo box.

The choice list Loop Level is automatically generated when inserting a combo box using Editor Tools. Note that a choice list generated in this way is not displayed under the Declarations node and cannot be modified by the user. For greater flexibility, such as giving names to each parameter or eigenfrequency value, you need to declare the choice list manually, as described in the previous section.

**Using a Combo Box to Change Times**

The time parameter list specified in a Time Dependent study step can be used in many places under the Results node. In an application, the individual time parameters can be accessed in a similar way to what was described in the last section for parameters, by using Model Data Access in combination with Editor Tools.
In the Settings window in the figure below, Model Data Access has been used to access the Time parameter list in a temperature plot.

In Editor Tools, a handle to the Time list is now available, as shown in the figure below.
By selecting **Input**, you can create a combo box using it as **Source**, as shown in the figure below.

The combo box can be used for multiple purposes, for example, to update a plot corresponding to a different time parameter. In order for a plot to automatically update when a user uses the combo box to select a new time parameter, add an event to the combo box at the bottom of its Settings window. In the figure below, a method `plot_T` is called for updating a temperature plot.

The line of code below shows the contents of the method `plot_T`:

```java
model.result("pg1").run();
```
The end result is a combo box in the application user interface, shown in the figure below, which automatically updates a temperature plot when the user selects a new value for the Time list.

**Using a Combo Box to Change Material**

Consider an application where combo boxes are used to select the material. In this case, an activation condition (see “Activation Condition” on page 134) can also be used for greater flexibility in the user interface design.

The figure below shows screenshots from an application where the user can choose between two materials, Aluminum or Steel, using a combo box named Material. A second combo box called Alloy shows a list of Aluminum alloys or Steel alloys, according to the choice made in the Material list.
The material choice is implemented in the embedded model using global materials and a material link, as shown below.

Each material is indexed with a string: `mat1`, `mat2`, ..., `mat5`. An event listens for changes to the value of the global variable `alloy`, where the value is controlled by a combo box. When the value is changed, the method listed below is run.

```plaintext
with(model.material('matlnk1'));
  set('link', alloy);
endwith();
```
The figure below shows the declaration of two string variables, \texttt{material} and \texttt{alloy}, which are controlled by the \texttt{Material} and \texttt{Alloy} combo boxes, respectively.

The application utilizes three choice lists: \textit{Aluminum Alloys}, \textit{Steel Alloys}, and \textit{Material}.

\textbf{Activation Condition}

An activation condition is used for the \textit{Aluminum Alloys} and \textit{Steel Alloys} choice lists, as shown in the figure below.
The **Settings** window for the **Material** combo box is shown below.

Note that the **Material** combo box uses the **material** string variable as its source. The **Material** choice list is used to define a discrete set of allowed values for the
material string variable. The Settings window for the Material choice list is shown below.

```
Settings
Choice List
Label:  Material
Name:   chooselist

List Content

<table>
<thead>
<tr>
<th>Value</th>
<th>Display name</th>
</tr>
</thead>
<tbody>
<tr>
<td>aluminum</td>
<td>Aluminum</td>
</tr>
<tr>
<td>steel</td>
<td>Steel</td>
</tr>
</tbody>
</table>
```
The **Settings** window for the **Alloy** combo box is shown in the figure below.
Note that the *Alloy* combo box uses both the *Aluminum Alloys* and the *Steel Alloys* choice lists. The choice list for *Aluminum Alloys* is shown in the figure below.
The activation condition for the Aluminum Alloys choice list is shown in the figure below.

**Using a Combo Box to Change Element Size**

When creating a combo box, you can use the Model Data Access functionality to reproduce the features of a combo box that exists within the Model Builder. For
example, consider an application where a combo box is used to change the element size in a mesh, as in the figure below.

Switch to the Model Builder and select the Mesh node (we assume here that the model has just a single mesh). In the Settings window of the Mesh node, select User-controlled mesh (if not already selected). In the Size node, directly under the Mesh node, select the option Predefined. Click Model Data Access in the ribbon. This gives access to the combo box for a predefined element size, as shown in the figure below.

Select the green check box to the left of the list to make it available as a source for a combo box in the Application Builder. Then, when you return to the Application Builder, you will find that the choice list for mesh size is now revealed as a potential Source in the Settings for a new combo box.
To insert the combo box object, you have two alternatives:

- Select **Combo Box** from the **Insert Object** menu in the ribbon. In the **Settings** window for the combo box, select the node **Predefined size (hauto)** in the **Source** section and then click the **Use as Source** button.

- In the **Editor Tools** window, select the node **Predefined size (hauto)** under the **Mesh > Size** node. Then right-click and select **Input**, as shown in the figure below.
The corresponding **Settings** window for the combo box is shown in the figure below.

Changing the **Initial value** to **From data source** ensures that the element size setting of the model, in this case **Normal**, is used as the default element size in the application. The choice list, **Predefined size (hauto)**, from the Model Builder is now selected as the choice list for your combo box in the Application Builder. This choice list does not appear as a choice list under the **Declarations** node of the application tree because it is being referenced from the Model Builder. Therefore, if you want a list with a more limited set of choices, you cannot edit it. Instead, you have to remove the predefined list as the **Source** of your combo box and create a new choice list of your own by declaring it under the **Declarations** node. For
example, you can create a choice list with three entries, as shown in the figure below.

To learn which values are used by the Element size list in the model, use Record a New Method and change the value from Normal to Fine, then to Coarse, and then back to Normal. Click Stop Recording and read the values in the autogenerated code. The Element size property name is `hauto` and the values for Fine, Normal, and Coarse are 4, 5, and 6, respectively, as implied by the automatically generated code shown in the lines below.

```plaintext
with(model.mesh('mesh1').feature('size'));
set('hauto', "4");
set('hauto', "6");
set('hauto', "5");
eンドwith();
```

The hauto property can also take non-integer values. For more information on Element size, see “Model Data Access for Buttons” on page 90.

**Using a Unit Set instead of a Choice List**

If the combo box will be used for the purpose of changing units, then a Unit Set can be used instead of a Choice List (you still select it in the Choice List section of the Settings window of the combo box).
An **Equation** object can display a LaTeX equation by entering the expression in the **Enter equation in LaTeX syntax** field.

A preview is shown of the rendered LaTeX syntax after leaving the text field.
Line

Use the **Line** form object to add a horizontal or vertical line to a form, which can be used, for example, to separate groups of form objects. For the horizontal line option, you can also add text that appears within the line.

![Line settings and position size](image)
Web Page

A Web Page object can display the contents of a web page as part of the user interface.

You can specify the page source in four different ways from the Source list:

- Use the default option Page to enter HTML code in a text area below the list, enclosed by the <html> and </html> start and end tags.
- Use the URL option to link to a web page on the Internet.
- Use the File option to point to a local file resource containing HTML code. Type the name of the file in the File field or click Browse to locate the file on the local file system.
- Use the Report option to embed an HTML report. The Browser preview is not active for this option.
Image

Use an **Image** form object to add an image to a form. An image object is different from a graphics object in that an image object is not interactive. Choose an image file from one of the library images, accessible from a drop-down list, or by clicking the **Add Image to Library and Use Here** button to select a file from the local file system. The figure below shows the **Settings** window for an image object referencing the image `cube_large.png`, defined in the **Libraries** node.

If you select an image file from your file system, this file will be embedded in the application and added to the list of **Images** under the **Libraries** node.

While you can change the x- and y-position of the image, the width and height settings are determined by the image file.

You can paste images from the clipboard to a form window by using Ctrl+V. For example, you can copy and paste images from the PowerPoint® slide presentation software. Such images will be added automatically to the **Images** library and embedded in the application. The names for pasted images are automatically set to: `pasted_image_1.png`, `pasted_image_2.png`, etc.

Video

A **Video** object embeds a video file in a form. The supported video file formats are MP4 (.mp4), OGV (.ogv), and WebM (.webm).
After added to a form, the Video object is represented, in the Form editor by an image, as shown in the figure below.

The figure below shows the Settings window for the Video object.

The available settings are:

- **Show video controls**
- **Start automatically**
- **Repeat**
- **Initially muted**

The option **Show video controls** enables the video controls such as Play and Stop. The option **Initially muted** is intended for the case where you want to play a video with the sound initially turned off. For example, if the video is set to start automatically, it can be useful to let the user choose whether the sound should be on. The user can enable the sound either from the video controls, if the check box **Show video controls** is selected, or by right-clicking in the video player.
**Progress Bar**

A **Progress Bar** object displays a customized progress bar, or set of progress bars, based on a value that is updated by a method. Use a progress bar to provide feedback on the remaining run time for an application. The figure below shows the **Settings** window of a progress bar object with one progress level.

Note that the built-in progress bar that is visible in the status bar of an application is controlled by the **Settings** window of the **Main Window** node. By default, the built-in progress bar shows the progress of the built-in COMSOL Multiphysics core algorithms, such as geometry operations, meshing, and solving. By using the `setProgress` method, you can customize the information shown in the built-in progress bar. For more information, see “Progress Methods” on page 296 and the **Application Programming Guide**.
The figure below shows the **Settings** window of a progress bar object with two progress levels.

![Settings window](image1)

In this example, the progress bar object is part of a form `progressform` used to present a two-level progress bar and a message log.

The figure below shows the corresponding progress dialog box in the running application.

![Progress dialog box](image2)
The figure below shows the form `progressform`.

![progressform](image)

The code segments below show typical built-in methods used to update the progress bar and the message log.

```plaintext
// show progress dialog box:
dialog("progressform");
setProgressBar("/progressform/progress1", 0, "Computing prong length.");

// code for iterations goes here:
lastProgress = 20;
// ...

// update message log:
message("Iteration Number: " + k);
message("Frequency: " + Math.round(fq*100)/100.00);
message("Length: " + Math.round(L1*100)/100.00);

// update progress bar:
setProgressInterval("Computing frequency", lastProgress, k*100/MAXITERATIONS);
// more code goes here:
// ...

// finished iterating:
setProgressBar("/progressform/progress1", 100);
closeDialog("progressform");
```

In the example above, the central functionality for updating the two levels of progress bars lies in the call
setProgressInterval("Computing frequency", lastProgress, k*100/MAXITERATIONS).

For detailed information on the built-in methods and their syntax, see “Progress Methods” on page 296 and the Application Programming Guide.

Log

The Log form object adds a log window that displays messages from the built-in COMSOL Multiphysics core algorithms, such as geometry operations, meshing, and solving.

The Include standard log toolbar check box is selected by default. When selected, the toolbar in the Log window that you see in the COMSOL Desktop is included in the application.

The figure below shows a part of an application user interface containing a log window.
The **Message Log** object adds a window where you can display messages to inform the user about operations that the application carries out. Implement this feature using the built-in `message` method with syntax: `message(String message)`. See also “GUI-Related Methods” on page 291.

The **Include standard message log toolbar** check box is selected by default. When selected, the toolbar in the **Messages** window that you see in the COMSOL Desktop is included in the application. The **Show COMSOL messages** check box is selected by default to enable messages from the built-in COMSOL Multiphysics core algorithms, such as geometry operations, meshing, and solving. Clear the check box to only allow messages from the application itself.
The figure below shows a customized message window with convergence information from a method (left) and the corresponding **Message Log** form object (right).

### Results Table

The **Results Table** object is used to display numerical results in a table.
The source of the results table data is one of the child nodes to Derived Values or Tables under Results. In the figure below, a Table node is used as the source (by selecting this option in the tree and then clicking Use as Source.)

**RESULTS TABLE TOOLBAR**

The Include standard results table toolbar check box is selected by default. When selected, a toolbar is included that provides the following buttons:

- **Full Precision**
- **Automatic Notation**
- **Scientific Notation**
- **Decimal Notation**
- **Copy Table and Headers to Clipboard**
- **Export**

The Export button is used to export to the following file formats:

- Text File (.txt)
- Microsoft® Excel® Workbook (.xlsx)
  - Requires LiveLink™ for Excel®
- CSV File (.csv)
- Data File (.dat)
CONTROLLING RESULTS TABLES FROM METHODS

There is a built-in method useResultsTable() for changing which table is shown in a particular results table form object. For more information on this built-in method, see “GUI-Related Methods” on page 291.

Form

A form object of the type Form is used to organize a main form in one or more subforms. To embed a subform, you create a link to it by selecting the form you would like to link to from the Form reference of the Settings window for the subform. The figure below shows an example where one of the cells of the form main has a link to the form input.
The figure below shows the referenced form input.

If you are using grid layout mode, then you can quickly create subforms using the Extract Subform button in the ribbon. See “Extracting Subforms” on page 105.
A **Form Collection** object consists of several forms, or panes, presented in a main form. In this example, there are four forms that appear as tabs in a single main window.

There are four different layout options. From the **Type** list, choose between:

- **Tabs**, the default setting, which displays the forms using tabbed panes.
- **List**, which displays a list to the left of the form panes, where you can select the form to display.
- **Sections**, which displays each form in a separate section.
- **Tiled or tabbed**, which displays the forms in one of two ways depending on the value of a Boolean variable. For more information, see the description later in this section.

In the **Panes** section, in the **Use selected forms as panes** list, each form represents a pane. These will be displayed in the application in the order they appear in the list. You can change the order by clicking the **Move Up** and **Move Down** buttons to the right.

You can control which tab (or list entry) is active by linking to a string variable in the section **Active Pane Selector**.

The string variable needs to be equal to one of the form names in the form collection, such as **temperature** or **conversion** in the example above. Otherwise, it will be ignored.
If you change the value of the pane selector pane in the above example, in a method that will be run at some point (a button method, for example), then the pane with the new value will be activated, as shown in the example below.

```java
pane="conversion"; /* Activate the conversion pane on completion of this method */
```

For a form collection with the **Type** set to **Sections**, the **Active Pane Selector** has no effect. Using an **Active Pane Selector** is optional and is only needed if you wish to control which tab is active by some method other than clicking its tab. To remove a string variable used as an **Active Pane Selector**, click the **Clear source** toolbar button under the tree.

The **Tiled or tabbed** option displays the forms in one of two ways depending on the value of a Boolean variable used as source in a **Tiled or Tabbed** section at the top of the Settings window.

The tabbed mode is identical to a form collection with the **Type** set to **Tabs**. In tiled mode, all the forms are shown simultaneously in a grid. The layout for the tiled mode can be controlled by the settings in the subsection **Tiled mode settings**.
**Card Stack**

A *Card Stack* is a form object that contains cards. A *Card* is another type of form object, one that is only used in the context of a card stack. Flip between cards in a card stack to show one at a time. You associate a card stack with a data source that controls which card to show. Each card specifies a value that is compared against the data source of the card stack. The card stack shows the first card with the matching value. If no cards match, nothing is shown.

**Using a Card Stack to Flip Between Graphics Objects**

Consider an application where the graphics shown to the user depend on the value of a scalar variable. This variable may change when a user clicks, for example, a radio button. The variable may also change depending on a computed value; for example, the value of a *Global Evaluation* node in the model tree.

The figure below shows the card stack object in the Form editor.

In this example, the card stack contains cards with graphics objects.
The figure below shows a card stack Settings window with five cards and a string variable display as its Active Card Selector.

By clicking a row in the table of cards in the Cards section, followed by clicking one of the toolbar buttons below the table, you can perform the following operations on cards:

- **Delete**
- **Edit**
- **Add Card**
- **Duplicate**

Each row in the table contains the name of the card in the Card column and their associated activating values in the Activating value column. The stack decides which cards to display based on their activating values. In this example, the activating values are the strings `geometry`, `velocity`, `particle1`, etc.
Clicking the **Add Card** button displays the following dialog box.

By default, the **Card type** is set to **Local**, which means that the card is defined locally in its containing card stack object. If the **Card type** is set to **Existing form**, then you can instead select one of the existing forms. The settings for an **Existing form** are accessed directly from the Form editor by clicking its node or by clicking the **Edit** button in the **Card** section of the corresponding card stack **Settings** window.

The figure below shows the **Settings** window of a **Card** as shown after clicking **Edit** in the table in the section **Cards**.

![Add Card dialog box](image)

![Settings window](image)
To access locally defined cards, right-click the card stack in a form window to select between the different cards in the card stack, as shown in the figure below.

From this menu, you can also duplicate cards. To edit cards, you can also use Alt-Click, which opens a dialog box that lets you select multiple cards at once.
The figure below shows card1 with its graphics form object.

**File Import**

A File Import object is used to display a file browser with an associated input field for browsing to a file or entering its path and name. It is used to enable file import by the user of an application at run time, when the file is not available in the application beforehand.

Consider an application where a CAD file can be selected and imported at run time, as shown in the figure below.

The corresponding File Import object is shown in the figure below.
The **Settings** window for the **File Import** object has a section **File Destination**. In this section, you can select any tree node that allows a file name as input. This is shown in the figure below, where the **Filename** for a geometry **Import** node is selected.

In this application, the **File types** table specifies that only CAD files are allowed. You can further control which **File types** are allowed by clicking the **Add** and **Delete**
buttons below the list of **File types**. Clicking the **Add** button displays the dialog box shown below:

![Add dialog box](image)

**ALTERNATIVES TO USING A FILE IMPORT OBJECT**

If an input field for the file path and name is not needed, then there are other methods for file import that allow a user to pick a file in a file browser. For example, you can use a menu, ribbon, toolbar item, or a button. In that case, you use an **Open File** command in the command sequence for that button or item.
The figure below shows the **Settings** window of a button used to import a CAD file.

A **File Import** object can also reference a **File** declaration. For more information, see “File” on page 135. For more information on file handling in general, see “Appendix C — File Handling and File Scheme Syntax” on page 263.

**Information Card Stack**

An **Information Card Stack** object is a specialized type of **Card Stack** object used to display information on the relationship between the inputs given by the user to an application and the solution. The figure below shows a portion of a running
application in which an information card stack is used together with information on the expected computation time.

Information

Expected computation time (finds): 15 s
Last computation time: 12 s

The corresponding form objects are shown below:
The figure below shows the Settings window where a string variable \texttt{solution\_state} is used as the source.

There are similarities with a Card Stack object, but for the Information Cards, each card has an icon and text. In the figure above, the string variable values \texttt{nosolution}, \texttt{inputchanged}, and \texttt{solutionexists} control which information card is shown.
In this example, the information card stack is accompanied by a data display object where a model tree information node for the **Expected Computation Time** is used as the source. The figure below shows its **Settings** window.

Note that information nodes in the model tree are only shown when working with the Application Builder. They are made available in the **Source** section in the **Settings** window for form objects, when applicable.

You can also find information nodes with **Last Computation Time** under each study. The information node **Last Computation**, found directly under the **Model** node, will correspond to the computation time for the last computed study.

Information nodes can be used as a source for input field objects, text objects, and data display objects. For input field objects and text objects, in order for the information nodes to be accessible, the **Editable** check box has to be cleared.
The Expected Computation Time take its data from the root node of the application tree, as shown below.

If the computation time is predominantly spent in a method, such as when the same study is called repeatedly, then you can manually measure the computation time by using the built-in methods `timeStamp` and `setLastComputationTime`. For more information, see “Date and Time Methods” on page 296.

**Array Input**

An Array Input object has an input table used to enter array or vector-valued input data. An array input object supports string arrays as data sources. You can add an optional label, symbol, and unit.
**Using an Array Input Object for 3D Point Coordinate Input**

Consider an application where the user enters 3D coordinates for a point where the stress is evaluated. The figure below shows a screenshot from an application with an array input, button, text label, and data display object.

![Screenshot of application with array input](image)

Von Mises stress at point: 40.16 MPa
The figure below shows the **Settings** window of the array input object.
The **Array Input** form object uses a **Source** named `samplecoords`, which is a **1D Array** of type **Double**. This array is created prior to the creation of the **Array Input** object by declaring an **Array 1D Double** with the following **Settings**.

![Settings window of the array input object](image)

<table>
<thead>
<tr>
<th>Name</th>
<th>Initial value</th>
<th>New element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>samplecoords</td>
<td>0.0,0.0,0.0</td>
<td>0.0</td>
<td>Sample coordinates</td>
</tr>
</tbody>
</table>

In the **Settings** window of the array input object:

- In the **Length** field, enter the length of the array as a positive integer. The default is 3.
- From the **Show vector as list**, choose **Table** (the default) to show the array components as a table, or choose **Components** to show each array component as a separate input field with a label.
- In the **Value** table, enter the initial values for the components in the array.
- The **Layout Options** section provides settings for adding optional labels and units to the array input.

In this example, when the user clicks the button labeled **Evaluate stress at point**, the following method is run:

```java
with(model.result().dataset("cpt1"));
set("pointx", samplecoords[0]);
set("pointy", samplecoords[1]);
set("pointz", samplecoords[2]);
endwith();
```

where the values `pointx`, `pointy`, and `pointz` will be used subsequently as coordinates in the evaluation of the stress.
Radio Button

A Radio Button object has a fixed number of options from which you can choose one. It is most useful when you have just a handful of options.

Using Radio Buttons to Select a Load

Consider an application where the user can select one of three predefined loads, as shown in the following figure.
The corresponding **Settings** window is shown below, where the global parameter $F$ is used as the source.

In the **Initial value** list, choose the manner in which the initial selection of the radio button should be made. The options are **From data source**, **First allowed value** (the default), and **Custom value**. For the **Custom value** option, select from a list of the allowed values given by the choice list.

In the **Choice List** section, you can add choice lists that contribute allowed values to the radio button object, where each valid value represents one radio button.
The radio button names are taken from the Display name column of their associated choice list. The figure below shows the choice list used in this example.

<table>
<thead>
<tr>
<th>Value</th>
<th>Display name</th>
</tr>
</thead>
<tbody>
<tr>
<td>300</td>
<td>High load (880 N)</td>
</tr>
<tr>
<td>150</td>
<td>Medium load (150 N)</td>
</tr>
<tr>
<td>50</td>
<td>Light load (53 N)</td>
</tr>
</tbody>
</table>

**Using a Unit Set instead of a Choice List**
If the radio button will be used for the purpose of changing units, then a Unit Set can be used instead of a Choice List (You still select it in the Choice List section of the Settings window of the radio button object).

**Selection Input**

In the Application Builder, you can allow the user of an application to interactively change which entities belong to an Explicit selection with a Selection Input object or a Graphics object. For more information on selections, see “Selections” on page 74. In the example below, the embedded model has a boundary condition defined.
with an **Explicit** selection. Both a **Selection Input** object and a **Graphics** object are used to let the user select boundaries to be excited by an incoming wave.

The user can select boundaries here by clicking directly in the graphics window corresponding to the **Graphics** object or by adding geometric entity numbers in a list of boundary numbers corresponding to a **Selection Input** object.

To make it possible to directly select a boundary by clicking on it, you can link a graphics object to an explicit **Selection** used to group boundaries, as shown in the figure below. Select the explicit selection and click **Use as Source**.
In the figure below, there are two explicit selections, **Excitation Boundary** and **Exit Boundary**, and the graphics object `graphics2` is linked to the selection **Excitation Boundary**.

![Diagram of settings and graphics content]

When a graphics object is linked directly to an explicit selection in this way, the graphics object displays the geometry and the user can interact with it by clicking on the boundaries. The boundaries will then be added (or removed) to the corresponding explicit selection.
To make it possible to select by number, you can link a selection input object to an explicit selection, as shown in the figure below.

In a selection input object, you can copy, paste, remove, clear, and zoom into selections.

You can choose to use a graphics object as the source of a selection without having any selection input object. You can also link both a graphics object and a selection input object to the same explicit selection.
A Text object is a text field with default text that is taken from a string variable or an Information node. The Settings window for a text object is shown below.

Select a string variable or Information node from the tree in the Source section and then click Use as Source. In the Value field, enter the initial text. By default, the Initial value text is taken from this field. To instead use the string variable for the Initial value text, change the Initial value setting to From data source.

The check box Editable is cleared by default. If selected, the text object can be used, for example, to type comments in a running application. If the text is changed by the user, it is stored in the string variable that is used as the data source, regardless of the Initial value setting.

The check box Wrap text is selected by default. Clear this check box to disable wrapping of the text. A scroll bar appears if the text does not fit.

For more information on Information nodes, see “Data Display” on page 85.
**List Box**

A **List Box** object is similar to a radio button object, except that it allows for the simultaneous selection of multiple options.

**Using a List Box to Superimpose Vibrational Modes**

Consider an application where the first six vibrational modes of a mechanical part can be superimposed and visualized by selecting them from a list box, as shown in the figure below.

As an alternative, the following figure shows that a list can be displayed as a dialog box.
The Settings window for the list box of this example is shown in the figure below.

The Select values in list allows you to choose between two alternatives, List box or Dialog, for displaying the list.

You can use any scalar or array declaration as a source. Select from the tree and click Use as Source. If you use a string array as the source, you can, in the running application, select more than one item in the list using Shift+Click or Ctrl+Click.
For other sources, you can only select one value from the list. This example uses a 1D string array `svar1D`. Its **Settings** window is shown below.

In the **Choice List** section, you can add choice lists that contribute allowed values to the list box. The figure below shows the choice list used in this example.

The vibrational modes 1–6 correspond to trivial rigid body modes and are not of interest in this application, hence the **Value** column starts at 7. The choice list allows you to hide the actual mode values in the model from the user by only displaying the strings in the **Display name** column. The first nonrigid body modes are named Mode 1, Mode 2, etc.
The method below uses the COMSOL Multiphysics operator `with()` to visualize the superimposed modes. This example is somewhat simplified, since it ignores the effects of amplitude and phase for the modes.

```java
String withstru="0";
String withstrv="0";
String withstrw="0";
for(int i=0;i<svar1D.length;i++){
    withstru=withstru + " + " + "with(" + svar1D[i] + ",u)";
    withstrv=withstrv + " + " + "with(" + svar1D[i] + ",v)";
    withstrw=withstrw + " + " + "with(" + svar1D[i] + ",w)";
}
with(model.result("pg7").feature("surf1").feature("def"));
setIndex("expr", withstru, 0);
setIndex("expr", withstrv, 1);
setIndex("expr", withstrw, 2);
endwith();
useGraphics(model.result("pg7"),"/form1/graphics8");
zoomExtents("/form1/graphics8");
```

Assuming the user selected the modes 1, 3, and 5 by using the list box, the method creates an expression `with(1,u)+with(3,u)+with(5,u)`. This expression is then used for the x-displacement (dependent variable `u`) in a displacement plot. In a similar way, the method automatically creates expressions for the variables `v` and `w` associated with the y- and z-displacement, respectively. Note that the command `with()` used in the results in the example above, is different from the built-in `with()` command used to shorten syntax that is described in “With, Get, and Set Methods” on page 300.

**Using a Unit Set instead of a Choice List**

If the list box will be used for the purpose of changing units, then a **Unit Set** can be used instead of a **Choice List** (You still select it in the **Choice List** section of the **Settings** window of the list box).
A **Table Object** represents a table with rows and columns that can be used to define input or output. The figure below shows an example of a running application with a table object used to accept input in three columns.

**Flow rate and fluid properties:**

<table>
<thead>
<tr>
<th>Flow rate (sccm)</th>
<th>Molecular weight (kg/mol)</th>
<th>Dynamic viscosity (Pa·s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.032</td>
<td>2E-5</td>
</tr>
<tr>
<td>200</td>
<td>0.028</td>
<td>1.7E-5</td>
</tr>
<tr>
<td>300</td>
<td>0.018</td>
<td>2.2E-5</td>
</tr>
<tr>
<td>1000</td>
<td>0.004</td>
<td>1.9E-5</td>
</tr>
<tr>
<td>250</td>
<td>0.022</td>
<td>2E-5</td>
</tr>
<tr>
<td>700</td>
<td>0.004</td>
<td>1.9E-5</td>
</tr>
<tr>
<td>2000</td>
<td>0.004</td>
<td>2.3E-5</td>
</tr>
<tr>
<td>600</td>
<td>0.028</td>
<td>1.7E-5</td>
</tr>
</tbody>
</table>

The figure below shows the corresponding form object and its **Settings** window.
In this example, the data source references three 1D string arrays. You can select any type of array as the source and then click **Use as Source**.

Three check boxes control the overall appearance of the table:

- **Show headers**
- **Automatically add new rows**
- **Sortable**

The **Automatically add new rows** check box ensures that an additional empty row is always available when a user is filling out a table. If all of the 1D string arrays, which are used as a source to the table, have nonempty values for **New element value** in their declaration **Settings** window, then this functionality is deactivated. In this case, new rows can only be added by clicking the **Add** button in the associated table toolbar, if such a button has been made available.

The **Sortable** check box makes it possible to sort the table with respect to a particular column by clicking the corresponding column header.

The **Sources** section contains a table with five columns:

- **Header**
- **Width**
- **Grow**
- **Editable**
- **Alignment**
- **Data source**

Each row in this table defines a column in the table object. The option **Grow** allows individual columns to grow when a form is resized. This option is only applicable to grid mode and if the **Horizontal alignment** of the table is set to **Fill**.
In the example, the string arrays define the initial values for the rows corresponding to the three columns, as shown in the figure below:

<table>
<thead>
<tr>
<th>Name</th>
<th>Initial values</th>
<th>New element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flow_rate</td>
<td>(100, 200, 300, 1000, 250, 700, 2000, 600)</td>
<td>100</td>
<td>Flow rate</td>
</tr>
<tr>
<td>molecular_weight</td>
<td>(0.032, 0.038, 0.146, 0.0504, 0.032, 0.0504, 0.964, 0.028)</td>
<td>0.032</td>
<td>Molecular weight</td>
</tr>
<tr>
<td>dynamic viscosity</td>
<td>(2E-5, 1.78E-5, 1.38E-5, 1.98E-5, 2E-5, 1.9E-5, 2.1E-5, 1.78E-5)</td>
<td>1.78E-5</td>
<td>Dynamic viscosity</td>
</tr>
</tbody>
</table>

**TOOLBAR**

In this section, you can select which toolbar buttons should be used to control the contents of the table. The **Position** list defines the location of the toolbar relative to the table and provides the following options:

- **Below**
- **Above**
- **Left**
- **Right**

To add a button to the toolbar, click the **Add Toolbar Button** below the table.
The following dialog box is then shown.

![Toolbar Buttons](image)

You can add the following buttons:

- **Move Up**
- **Move Down**
- **Add**
- **Delete**
- **Clear Table**
- **Clear Table and Load from File**
- **Load from File**
- **Save to File**

In addition, you can add customized buttons by clicking **Custom Button** in the **Toolbar Buttons** dialog box. The figure below shows the **Edit Custom Toolbar**
**Button** dialog box used to define a customized button. In this case, the button **Process 1** is used to set default values for a certain process.

The **Choose commands to run** section is similar to that of menu, ribbon, and toolbar items, as well as buttons.

The **Load from File** and **Save to File** buttons are used to load and save from/to the following file formats:

- Text File (.txt)
- Microsoft® Excel® Workbook (.xlsx)
  - Requires LiveLink™ for Excel®
- CSV File (.csv)
- Data File (.dat)
This is shown in the figure below.

![File selection dialog box](image)

The allowed separators are comma, semicolon and tab for CSV files, and space and tab for DAT and TXT files.

**Slider**

A *Slider* is a form object for choosing numerical input using a slider control.

**Using a Slider to Change the Magnitude of a Structural Load**

Consider an application where the magnitude of a load can be changed by a slider control, such as in the figure below.

![Slider example](image)

In this example, the slider is accompanied by an input field that is used to display the selected value.
The *Settings* window of the slider is shown in the figure below.

In this example, the slider uses a global parameter $F$ as its source. You can select any parameter, variable, or declared scalar variable as a source. Select from the tree and click **Use as Source**.

From the **Value type** list, choose *Integer* or *Real* (default), depending on the type of data in the data source for the slider.

You determine the range of values for the data source by defining the **Maximum value**, **Minimum value**, and **Number of steps** for the slider. You can also set a **Tooltip** that is shown when hovering over the slider. The **Append unit to number** option lets you associate a unit with the slider. This unit is appended to the number using the standard bracket notation, such as $[\text{N}]$, before being passed as a value to the source variable. In the example above, the input field and the slider both have the setting **Append unit to number** activated. As an alternative to **Append unit to number**, you can choose **Append unit from unit set**. See “Unit Set” on page 136.
for more information.
In the **Initial value** list, select **From data source** or **Custom value** for the initial value for the slider.

**Hyperlink**

A **Hyperlink** object embeds a hyperlink in a form. The figure below shows an example of a hyperlink.

![COMSOL Web Page](image)

The figure below show the corresponding **Settings** window.

<table>
<thead>
<tr>
<th>Name</th>
<th>hyperlink1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>COMSOL Web Page</td>
</tr>
<tr>
<td>URL</td>
<td><a href="http://www.comsol.com">www.comsol.com</a></td>
</tr>
</tbody>
</table>

- **Position and Size**
  - Width: 135
  - Height: 15
  - Position x: 20
  - Position y: 400

- **Appearance**
  - Background color: Transparent
  - Font: Default font
  - Font size: Default size

- **Visible**
- **Enabled**

The **Hyperlink** object supports the types of URLs that you can use in a web browser, including:

- **Web Page**: When a user clicks the hyperlink for a web page, it opens in the user’s default browser. The URL string needs to be on the form `protocol://address`, where protocol is the transmission protocol; for
example, HTTP or HTTPS. The web address can be partial or complete, but it is recommended to use a complete web address.

- Email: An email address is specified on the form `mailto:emailaddress`. This will launch the user’s default email application program and prepare a new message where the To field is set to the address specified. This way of interactively sending an email from a COMSOL application is different from using the built-in method. For more information on the built-in methods for email, see “Email Methods” on page 288.

**Toolbar**

A **Toolbar** object contains the specifications of a toolbar with toolbar buttons. The figure below shows a toolbar with buttons for **Save as**, **Compute**, and **Plot**.

The **Settings** window for this toolbar is shown in the figure below.

Each row in the **Toolbar Items** table contains either an **item** corresponding to a toolbar button or a **separator**. Use the buttons below the table to add items or separators, change row order, or delete a row. Click the **Edit** button to display the
Settings window associated with each row. The figure below shows the Settings window of item1, the Save As item.

The text in the Text field will be shown as a tooltip when hovering over the toolbar button. The Icon list, the Keyboard shortcut field, and the Choose commands to run tree represent the same functionality as a button object. For more information, see “Button” on page 51.

Spacer

A Spacer object is invisible in the user interface and is only used when working in grid layout mode. It defines a space of fixed size that you can use to ensure that neighboring form objects have enough space to show their contents. Typically, you would use a spacer next to a table or graphics object to ensure that they are rendered properly. If the user resizes the window so that it becomes smaller than
the size of the spacer, the effective size of the window is maintained by displaying scroll bars. The figure below shows the **Settings** window of a spacer object.
Appendix B — Copying Between Applications

Many nodes in the application tree can be copied and pasted between applications, including: forms, form objects, menu items, methods, Java® utility methods, external libraries, file declarations, choice list declarations, menus, menu items, ribbon sections, ribbon tabs, and ribbon items.

When you copy and paste forms, form objects, and items between applications, the copied objects may contain references to other objects and items. Such references may or may not be meaningful in the application to which it is copied. The following set of rules apply when objects are pasted from the clipboard:

- A declaration referenced in a form object or menu item is included when copying the object, but is not necessarily pasted. It is only pasted if there is no compatible declaration present. If a compatible declaration exists, that is used instead. A compatible declaration is defined as one having the same name and type. For example, a string declaration is not compatible with an integer declaration. An existing declaration may have an invalid default, but no such check is done when pasting.
- A referenced global parameter may have a different unit, but will still be considered compatible.
- A form or form object directly referenced from another form object is not included automatically when copying objects. The direct reference will point to an existing object if it has the same name. If the original reference is among the copied objects, then that object will be used in the reference instead of any existing objects having the same name. The name of the copied reference will be changed to avoid name collisions.
- No objects in the model tree will be automatically copied, for example, a graphics object referring to a geometry or an input field referring to a low-level setting exposed by Model Data Access. If the reference points to an object that exists in the model tree of the target application, then that reference will be used.
- References to nonexisting objects will be attempted to be removed when pasted. An exception is command sequences in buttons, where all commands are kept and marked as invalid if they point to a nonexisting reference.
- Local methods are included in the copy-paste operation. However, no attempt is made to update the code of the method. This also applies when copying a global method.
- Arguments to commands in the command sequence of a button or a menu item will be left as is.
• All image references are automatically copied and added to the image library when applicable. If there is an existing image with the same name, it will be used instead of the copied version.

• No files, sounds, or methods are automatically copied if referenced to. However, methods can be copied and pasted manually.

• All pasted objects that have a name that conflicts with that of an existing object will be renamed. Any references to the renamed object from other pasted objects will be updated.
Appendix C — File Handling and File Scheme Syntax

The handling of files may be an important feature of an application. For example, the application may require a spreadsheet file with experimental data as input, a CAD file to be imported, or a report to be generated and exported. The Application Builder provides tools for reading and writing entire files or portions of a file. The way that this is done will vary depending on the system where the application is running. The file system may be different on the computer running COMSOL Multiphysics, where the application is developed, and on the computer where COMSOL Server is installed and the application will run once it is deployed.

**File Handling with COMSOL Server**

In general, you cannot read and write files to local directories when running applications with a web browser or the COMSOL Client for Windows®. The application and its methods are run on the server and have no knowledge of the client file system (where the web browser or COMSOL Client is run). However, there are techniques for transferring files to and from the client file system when running an application both with a web browser and the COMSOL Client.

A **File Import** object can be used to ask the user for a file. The user then browses to a file on the client file system, which is then uploaded to the COMSOL Server file system and becomes available to the application and its methods. This can be used, for example, to provide a CAD file or an experimental data file from the user at run time. This is covered in the section “File Import” on page 268.

In a command sequence of, for example, a button, you can export data generated by the embedded model by running a subnode of the **Export** or **Report** nodes. This is covered in the section “File Export” on page 276.
**SAVING AND OPENING FILES USING FILE COMMANDS**

In the editor tree used in a command sequence, the **File Commands** folder contains commands to save and load applications and files, as well as exiting an application.

The command **Open File** will pick any file from the server produced by a method, the model, or embedded with the application, and open it using the associated application on the client. This can be used, for example, to open a PDF file in the client file system, or show a text file or an image exported from the model on the client side. In the figure above, an **Open File** command is used to open the PDF documentation for an application. The corresponding PDF file is embedded in the application by being stored in the **Libraries > Files** node. Files located there are referenced using the `embedded://` file scheme syntax described in the next section, “File Scheme Syntax” on page 266.
To open files from a method, use the built-in method `fileOpen`; see also “Operating System Methods” on page 288.

To save a file, use the command `Save File As`, which is similar to `Open File`. It will take any file from the server file system and display a `Save As` dialog box to the user where the user can browse to a client location to save the file. This is similar to downloading files from a link within a web browser. In the figure below, a `Save File As` command is used to save a CAD model that is stored in the `Libraries > Files` node.

![Choose Commands to Run](image)

To save files from a method, use the built-in method `fileSaveAs`; see also “GUI Command Methods” on page 294. For more information on saving and exporting files, see “File Export” on page 276.

The `Save Application` and `Save Application As` commands are available for use in the command sequence for certain form objects. The `Save Application As` command will display a `Save As` dialog box where the user can specify a client path where the entire application will be saved.

Similarly, the `Save Application on Server` and `Save Application on Server As` commands are available to save the entire application on the server file system. For information on the corresponding built-in methods, see “GUI Command Methods” on page 294.

In summary, both uploading and downloading files from the client file system is supported, but the application can never do it silently in the background without the user browsing to the source or destination location of the file.

**MODEL COMMANDS**

In the editor tree used in a command sequence, the `Model Commands` folder contains two commands: `Clear all solutions` and `Clear all meshes`. Use these
commands to make the MPH file size smaller before saving an application by erasing solution and mesh data, respectively.

**File Scheme Syntax**

To make applications portable, the Application Builder allows you to use virtual file locations using file schemes. A file scheme can be seen as a pointer to a file on the file system, but the application does not need to know where the file is actually stored.

Different file schemes exist for different purposes:
- The **user** file scheme is for files that should be persistent between different runs of an application by the same user.
- The **common** file scheme behaves in the same way, but is for files that should be shared between all users.
- The **temp** file scheme is for files that should be removed as soon as the application is closed.
• The **embedded** file scheme is used to store files in the application itself. This can be useful if you want to make the application self-contained and send it to someone else.

• The **upload** file scheme is for files that are uploaded to the application by the user at runtime, such as a CAD-file to which the user browses.

The table below summarizes all available file schemes.

<table>
<thead>
<tr>
<th>SCHEME</th>
<th>REFERS TO</th>
<th>DEFAULT PATH</th>
<th>TYPICAL USAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>embedded://</td>
<td>Files embedded in the application using Libraries &gt; Files</td>
<td>N/A</td>
<td>Experimental data, CAD files, mesh files, interpolation data</td>
</tr>
<tr>
<td>upload://</td>
<td>Files to be uploaded by the user at runtime</td>
<td>Determined by the Target directory in the Settings window of the File declaration</td>
<td>Experimental data, CAD files, mesh files, interpolation data</td>
</tr>
<tr>
<td>temp://</td>
<td>Files in a random temporary directory, which is unique for each started application instance. These files are deleted when the application is closed.</td>
<td>A random subdirectory to the folder for temporary files, as determined by the settings in Preferences &gt; Files</td>
<td>Temporary files produced by command sequences or methods, or output to be saved on the client (for use with COMSOL Server)</td>
</tr>
<tr>
<td>user://</td>
<td>Files in a directory shared by all applications for the current user</td>
<td>Determined by the settings in Preferences &gt; Files</td>
<td>Output from methods to be saved between sessions</td>
</tr>
<tr>
<td>common://</td>
<td>Files in a directory shared by all users</td>
<td>Determined by the settings in Preferences &gt; Files</td>
<td>Files shared between many users or applications</td>
</tr>
</tbody>
</table>

For more information on files in the Libraries node accessible by the `embedded://` syntax, see “Libraries” on page 175.

The table below summarizes the usage of the different file schemes. In the table, a check mark means that this scheme is available and (r) means that it is the recommended scheme.

<table>
<thead>
<tr>
<th>USAGE</th>
<th>EMBEDDED</th>
<th>UPLOAD</th>
<th>TEMP</th>
<th>USER</th>
<th>COMMON</th>
</tr>
</thead>
<tbody>
<tr>
<td>File is used as input</td>
<td>√ (r)</td>
<td>√</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>File is output</td>
<td></td>
<td></td>
<td>√ (r)</td>
<td>√</td>
<td></td>
</tr>
<tr>
<td>Method reading a file</td>
<td>√ (r)</td>
<td>√</td>
<td>√</td>
<td>√</td>
<td>√</td>
</tr>
</tbody>
</table>
You can set the preferences for the paths to temporary, user, and common files in the Files page of the Preferences dialog box, which is accessible from the File menu, as shown in the figure below.

### File Import

#### CAD Import using the Model Tree and a File Import Object

A File Import object is used to display a file browser with an associated input field for browsing to a file or entering its path and name. It is used to enable file import by the user of an application at run time, when the file is not available in the application beforehand. You can directly link a File Import object to a file Import node in the model tree; for example, a CAD Import node. Consider an application where a CAD file can be selected and imported at run time, as shown by the figure below.

The corresponding File Import object is shown in the figure below.
The **Settings** window for the **File Import** object has a section **File Destination**. In this section, you can select any tree node that allows a file name to be input. This is shown in the figure below, where the **Filename** for the **Import** node is selected.

If you do not wish to use a **File Import** object, you can directly reference a **Filename** from a button or an item in a menu, ribbon, or toolbar.
The figure below shows a ribbon item used for geometry import together with its \textit{Settings} window.
In the Settings window above, the command Import file to Import 1 will open a file browser for the user to select a file, as shown in the figure below.

The subsequent commands build and plot the geometry, zoom out using zoom extents, and finally set the value of a string variable (in this case used to control a card stack).

For more information on the File Import object, see “File Import” on page 228.

FILE IMPORT IN METHODS

Continuing the example of the previous section, assume that we click Convert to New Method in the Settings window. The corresponding lines of code show how CAD import can be accomplished from a method:

```plaintext
importFile(model.geom('geom1').feature('imp1'), "filename");
model.geom("geom1").run();
useGraphics(model.geom("geom1"), "form1/cardstack1/card3/graphics1");
zoomExtents("form1/cardstack1/card3/graphics1");
mode = "Visualization";
```

The first line illustrates using the built-in method importFile. For more information on the method importFile and other methods for file handling, see “File Methods” on page 286.

FILE ACCESS AND FILE DECLARATIONS

At the bottom of the Settings window of a File Import object, you can see which file scheme syntax to use to access an imported file from a method (next to Access
using:). The figure below shows an example where a **File Destination** and **Filename** are used.

The file scheme syntax, `upload:///geom1/imp1/filename`, needs to be used whenever accessing this file.

As an alternative, you can use a **File** declaration under the **Declarations** node. (However, **File** declarations are primarily used for file import from method code.) In this case, the file chosen by the user can be referenced in a form object or method using the syntax `upload:///file1, upload:///file2, etc.` The file name handle (`file1, file2, etc.`) can then be used to reference an actual file name picked by the user at run time. See also “File” on page 135.

This syntax can also be used in any file browser text fields within the Model Builder nodes. The figure below shows a file reference used in the **Filename** field of the **Import** model tree node for a model using geometry import.

However, a quicker way is to link a file import object directly to the **Filename** field, as described previously in the section “CAD Import using the Model Tree and a File Import Object” on page 268.
IMPORTING EXPERIMENTAL DATA

Consider an application where the user is providing a file with experimental data at run time. The figure below shows the file import object of such an application as it appears in grid layout mode.

The figure below shows the Settings window of the corresponding file import object and its link to a file declaration.
In this application, the **File types** table specifies that only CSV files are allowed. The **Settings** window for the **File** declaration is shown in the figure below.

The file declaration serves as the “destination” of the imported data, which is written to the file `upload:///experimental.csv`.

Note that the file extension `.csv` used in the declaration is optional and that the file picked by the user at run time can have any name. For example, the file name picked at run time can be `my_data.csv`, but when referenced in method code, the abstract file handle name `experimental.csv` is always used.

In order to make it possible to run the application without having to first provide experimental data, a file containing default experimental data is embedded in the application. This default data file is used by the application by accessing it with the `embedded:///` file scheme syntax, as shown in the figure below.
In this example, which uses the Optimization Module, the application performs a least-squares fit to the experimental data.

The following method handles the logic to determine if user-provided experimental data files exist or if the default data set should be used.

```cpp
if (exists("upload:///experimental.csv")) {
    with(model.physics("opt").feature("glsobj1"));
    set("filename", "upload:///experimental.csv");
    endwith();
} else {
    String s_data = confirm("No experimental data file was uploaded. Do you want to use the embedded data?", "Experimental Data", "Yes", "Cancel Parameter Estimation");
    if (s_data.equals("Cancel Parameter Estimation")) {
        return;
    }
}
```

If a user-provided file exists, the code replaces `embedded:///experimental_default.csv` with `upload:///experimental.csv` in the physics interface `glsobj1`. 
**File Export**

**FILE EXPORT USING THE MODEL TREE**

In a command sequence of, for example, a button, you can export data generated by the embedded model by running a subnode of the *Export* or *Report* nodes. In the model tree, the *Export* node may contain the following types of subnodes for file export:

- Data
- Plot
- Mesh
- Table
- 3D Image
- 2D Image
- 1D Image
- Animation

The *Settings* window for each of these nodes contains an *Output* section with a field for *Filename*. The figure below shows the *Settings* window for an *Export > Plot* node.

![Settings window for an Export > Plot node](image)

You can leave the *Filename* field blank, as shown in the figure above. In the command sequence of, for example, a button, you can run the corresponding
Export > Plot node and, at run time, it will open a file browser window for the user to select a location and file name, as seen in the figure below.

While developing an application, you may need to use the Model Builder repeatedly to check the exported data. In this case, you can use the Filename field for a test file and, by selecting the Always ask for filename check box, a file browser will still be opened at run time.

In a similar way to the Export subnodes, each Report subnode has a Format section with a Filename field, as seen in the figure below.

By running a Report subnode, a file browser window is opened for the user to select a location and file name for the report.

For more detailed control over file import and export, you can instead use a file scheme.

**File Export to a Temporary File**

Some applications may need to produce temporary files, and this is accomplished by using the temp:// file scheme. The temporary files are stored in a random temporary directory, which is unique for each started application instance. These files are deleted when the application is closed. Temporary files can be produced by command sequences or methods, or output to be saved on the client when used with COMSOL Server.
The example below shows the Settings window of an Export > Plot node that is used to export plot data as numerical values.

The Filename in its Output section is set to temp://lineplot.txt. To save the plot to disc in this example, a button is created. In the Settings window for the button, in the section Choose Commands to Run, first create the output graph file by choosing the Export > Plot node created above and clicking Run. Second, choose GUI Commands > File Commands > Save File As and click Run again.
In the **Output** section of the button **Settings**, set the filename to the name of the temporary file created by the **Export Plot** command, in this case, `temp:///lineplot.txt`. 
The **Save File As** command provides a dedicated **Edit Argument** dialog box with easy access to all embedded files as well as shortcuts for all file schemes.

**CREATING REPORTS USING LOW-LEVEL FUNCTIONALITY**

This section describes creating reports using low-level functionality. For a more direct method, see “File Export” on page 276.

The example below shows an application where a report in the Microsoft® Word® format (.docx) can be saved by the user. The figure below shows a tab in the ribbon of the application. In this tab, there is a **Report** button in the **Documentation** section.
The associated application tree node is shown in the figure below.

![Application Builder](image)

The following figure shows how the syntax `user://file` was used in the **Filename** field in the **Settings** window of the **Report** node of the Model Builder.

![Model Builder](image)

In this application, the check box **Open finished report** is selected, which means that the Word® document will open after the report has been created. The user of the application can then save the report from the Word® file menu.
In this example, the file scheme common:/// could have been used in the same way. The user and common file schemes are primarily useful when the same files are used repeatedly by an application.

The figure below shows the Settings window of the Report ribbon item.

![Settings window](image)

The method `b_report` contains the following code:

```java
if(length(information_card)>0) {
    alert("New input data. Compute to update results first.");
}
else {
    model.result().report("rpt1").run();
}
```

The file scheme syntax can also be used directly in methods. The code below is from a method used to export an HTML report.

```java
String answerh = request("Enter file name","File Name", "Untitled.html");
if(answerh != null){
    model.result().report("rpt1").set("format","html");
    model.result().report("rpt1").set("filename","user:///"+answerh);
    model.result().report("rpt1").run();
}
Appendix D — Keyboard Shortcuts

The table below lists the keyboard shortcuts available in the Application Builder.

<table>
<thead>
<tr>
<th>SHORTCUT</th>
<th>ACTION</th>
<th>APPLICATION BUILDER</th>
<th>FORM EDITOR</th>
<th>METHOD EDITOR</th>
</tr>

</table>
Appendix E — Built-in Method Library

This appendix lists all of the built-in methods available in the Method editor, except for methods that operate on the model object and the application object. For detailed information on using the built-in methods and for full information on the syntax used, see the Application Programming Guide and the Programming Reference Manual.

As an alternative method of learning the syntax of these methods, you can use code completion by typing the name of the method and then use Ctrl+Space. A window will open with information on the syntax and method signature.

Model Utility Methods
The model utility methods make it possible to load the model object part of an MPH file into a method for further processing.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>createModel</td>
<td>Creates a new model with a given tag.</td>
</tr>
<tr>
<td>removeModel</td>
<td>Removes a model. The embedded model cannot be removed.</td>
</tr>
<tr>
<td>modelTags</td>
<td>Returns an array of model tags for all loaded models, including the embedded model.</td>
</tr>
<tr>
<td>uniqueModelTag</td>
<td>Returns a model tag that is not in use.</td>
</tr>
<tr>
<td>getModel</td>
<td>Returns a model with a specified tag.</td>
</tr>
<tr>
<td>loadModel</td>
<td>Loads a model with a specified tag from a file.</td>
</tr>
<tr>
<td>loadProtectedModel</td>
<td>Loads a password protected model with a specified tag from a file.</td>
</tr>
<tr>
<td>loadRecoveryModel</td>
<td>Loads a model from a recovery directory/folder structure.</td>
</tr>
<tr>
<td>saveModel</td>
<td>Saves a model to a file. The filename can be a file scheme path or, if allowed by security settings, a server file path.</td>
</tr>
</tbody>
</table>
## File Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>readFile</code></td>
<td>Returns the contents in a given file as a string.</td>
</tr>
<tr>
<td><code>openFileStreamReader</code></td>
<td>Returns a <code>CsReader</code> object that can be used to read line-by-line or character-by-character from a given file name.</td>
</tr>
<tr>
<td><code>openBinaryFileStreamReader</code></td>
<td>Returns a <code>CsBinaryReader</code> object that can be used to read from a given file byte-by-byte.</td>
</tr>
<tr>
<td><code>readMatrixFromFile</code></td>
<td>Reads the contents of the given file into a double matrix. The file has the same spreadsheet-type format as available in the model tree Export node.</td>
</tr>
<tr>
<td><code>readStringMatrixFromFile</code></td>
<td>Reads the contents of the given file into a string matrix. The file has the same spreadsheet-type format as available in the model tree Export node.</td>
</tr>
<tr>
<td><code>readCSVFile</code></td>
<td>Reads a file with comma-separated values (CSV file) into a string matrix. It expects the file to use the RFC 4180 format for CSV.</td>
</tr>
<tr>
<td><code>writeFile</code></td>
<td>Writes array <code>data</code> to a given file. If the spreadsheet format is used, then the data can be read by <code>readMatrixFromFile</code> or <code>readStringMatrixFromFile</code>.</td>
</tr>
<tr>
<td><code>openFileStreamWriter</code></td>
<td>Returns a <code>CsWriter</code> object that can write to a given file.</td>
</tr>
<tr>
<td><code>openBinaryFileStreamWriter</code></td>
<td>Returns a <code>CsBinaryWriter</code> object that can be used to write to a given file byte-by-byte.</td>
</tr>
<tr>
<td><code>writeCSVFile</code></td>
<td>Writes a given double or string array to a CSV file. The RFC 4180 format is used for the CSV.</td>
</tr>
<tr>
<td><code>exists</code></td>
<td>Tests whether a file with a given name exists.</td>
</tr>
<tr>
<td><code>deleteFile</code></td>
<td>Deletes a file with a given name if it exists. The file is deleted on the server.</td>
</tr>
<tr>
<td><code>copyFile</code></td>
<td>Copies a file on the server. Both the source and target names can use file scheme paths.</td>
</tr>
<tr>
<td><code>importFile</code></td>
<td>Displays a file browser dialog box and uploads the selected file to the file declaration with the given <code>name</code>. Alternatively, it uploads the selected file to the Filename text field in a given model object entity.</td>
</tr>
<tr>
<td><code>writeExcelFile</code></td>
<td>Writes the given string array <code>data</code> starting from a specified cell in a specified sheet of an Excel file.</td>
</tr>
<tr>
<td><code>readExcelFile</code></td>
<td>Reads a specified sheet of an Excel file, starting from a specified cell, into a 2D string array.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>getFilePath</code></td>
<td>Returns the absolute server file path of the server proxy file corresponding to a certain file scheme path, or null if the server proxy file for the given path does not exist. This method can be used to pass the path to, for example, a file using the <code>temp://</code> scheme to external code or an application.</td>
</tr>
<tr>
<td><code>getClientFileName</code></td>
<td>Returns the original name of an uploaded file on the client file system (or null if there is no uploaded file matching the given file scheme path). This method is only useful for providing user interface feedback; for example, to get information on which uploaded file is being used. There is no guarantee that the original file would still exist on the client or even that the current client would be the same as the original client.</td>
</tr>
<tr>
<td><code>getClientFilePath</code></td>
<td>Returns the original path of an uploaded file on the client file system (or null if there is no uploaded file matching the given file scheme path). This method is only useful for providing user interface feedback; for example, to get information on which uploaded file is being used. There is no guarantee that the original file would still exist on the client or even that the current client would be the same as the original client.</td>
</tr>
</tbody>
</table>
Operating System Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>executeOSCommand</td>
<td>Executes the OS command with a given command (full path) and parameters. When applicable, the command is run server side.</td>
</tr>
<tr>
<td>fileOpen</td>
<td>Opens a file with the associated program on the client. See also the section “File Methods”.</td>
</tr>
<tr>
<td>getUser</td>
<td>Returns the username of the user that is running the application. If the application is not run from COMSOL Server, then the value of the preference setting General&gt;Username&gt;Name is returned.</td>
</tr>
<tr>
<td>openURL</td>
<td>Opens a URL in the default browser on the client.</td>
</tr>
<tr>
<td>playSound</td>
<td>Plays a sounds on the client.</td>
</tr>
</tbody>
</table>

Email Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>emailFromAddress</td>
<td>Returns the email from address from the COMSOL Server or preferences setting.</td>
</tr>
<tr>
<td>sendEmail</td>
<td>Sends an email to the specified recipient(s) with the specified subject, body text, and zero or more attachments created from Report, Export, and Table nodes in the embedded model.</td>
</tr>
<tr>
<td>userEmailAddress</td>
<td>Returns the user email address(es) corresponding to the currently logged in user; or an empty string if the user has not configured an email address.</td>
</tr>
</tbody>
</table>

Email Class Methods

The class EmailMessage can be used to create custom email messages.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>EmailMessage</td>
<td>Creates a new EmailMessage object.</td>
</tr>
<tr>
<td>EmailMessage.setServer</td>
<td>Sets the email (SMTP) server host and port to use for this email message.</td>
</tr>
<tr>
<td>EmailMessage.setUser</td>
<td>Sets the username and password to use for email (SMTP) server authentication. This method must be called after the setServer method.</td>
</tr>
<tr>
<td>EmailMessage.setSecurity</td>
<td>Sets the connection security type for email (SMTP) server communication.</td>
</tr>
<tr>
<td>EmailMessage.setFrom</td>
<td>Sets the from address.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EmailMessage.setTo</td>
<td>Sets the to addresses.</td>
</tr>
<tr>
<td>EmailMessage.setCc</td>
<td>Sets the cc addresses.</td>
</tr>
<tr>
<td>EmailMessage.setBcc</td>
<td>Sets the bcc addresses.</td>
</tr>
<tr>
<td>EmailMessage.setSubject</td>
<td>Sets the email subject line. Note that newline characters are not allowed.</td>
</tr>
<tr>
<td>EmailMessage.setBodyText</td>
<td>Sets the email body as plain text. An email can contain both a text and an HTML body.</td>
</tr>
<tr>
<td>EmailMessage.setBodyHtml</td>
<td>Sets the email body as HTML text. An email can contain both a text and an HTML body.</td>
</tr>
<tr>
<td>EmailMessage.attachFile</td>
<td>Adds an attachment from a file. The attachment MIME type is determined by the file name extension.</td>
</tr>
<tr>
<td>EmailMessage.attachFile</td>
<td>Adds an attachment from a file with a specified MIME type.</td>
</tr>
<tr>
<td>EmailMessage.attachFromModel</td>
<td>Adds an attachment created from a report, export, or table feature in the model.</td>
</tr>
<tr>
<td>EmailMessage.attachText</td>
<td>Adds a text attachment with a specified sub-MIME type, such as plain or HTML.</td>
</tr>
<tr>
<td>EmailMessage.attachBinary</td>
<td>Adds an attachment from a byte array with a specified MIME type.</td>
</tr>
<tr>
<td>EmailMessage.send</td>
<td>Sends the email to the email (SMTP) server. An email object can only be sent once.</td>
</tr>
</tbody>
</table>
EMAIL PREFERENCES

To set preferences for an outgoing email (SMTP) server, open the Email page of the Preferences dialog box, as shown in the figure below.

COMSOL Server provides a similar set of email preferences.
<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Call a method directly</td>
<td>Call a method from the Methods list by using its name; for example, method1(), method2().</td>
</tr>
<tr>
<td>callMethod</td>
<td>Alternate way to call a method from the Methods list; used internally and in cases of name collisions.</td>
</tr>
<tr>
<td>useGraphics</td>
<td>Plots a given entity (Plot Group, Geometry, Mesh, or Explicit Selection) in the graphics form object given by a name or name path in the second argument.</td>
</tr>
<tr>
<td>useForm</td>
<td>Shows the form with a given name in the current main window. Equivalent to the use method of a Form object; see below.</td>
</tr>
<tr>
<td>closeDialog</td>
<td>Closes the form, shown as a dialog box, with a given name.</td>
</tr>
<tr>
<td>dialog</td>
<td>Shows the form with a given name as a dialog box. Equivalent to the dialog method of a Form object; see below.</td>
</tr>
<tr>
<td>alert</td>
<td>Stops execution and displays an alert message with a given text.</td>
</tr>
<tr>
<td>alert</td>
<td>Stops execution and displays an alert message with a given text and title.</td>
</tr>
<tr>
<td>confirm</td>
<td>Stops execution and displays a confirmation dialog box with a given text and title. It also displays two or three buttons, such as “Yes”, “No”, and “Cancel”.</td>
</tr>
<tr>
<td>error</td>
<td>Stops execution and opens an error dialog box with a given message.</td>
</tr>
<tr>
<td>request</td>
<td>Stops execution and displays a dialog box with a text field, requesting input from the user.</td>
</tr>
<tr>
<td>message</td>
<td>Sends a message to the message log if available in the application.</td>
</tr>
<tr>
<td>evaluateToResultsTable</td>
<td>Evaluates a given entity, a Derived Value, in the table object given by the name or name path in the second argument, which will then be the default target for the evaluations of the Derived Value. If the third argument is true, the table is cleared before adding the new data. Otherwise, the data is appended.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>evaluateToDoubleArray2D</td>
<td>Evaluates the given entity, a Derived Value, and returns the nonparameter column part of the real table that is produced as a double matrix. All settings in the numerical feature are respected but those in the current table connected to the numerical feature are ignored.</td>
</tr>
<tr>
<td>evaluateToIntegerArray2D</td>
<td>Evaluates the given entity, a Derived Value, and returns the nonparameter column part of the real table that is produced as an integer matrix. All settings in the numerical feature are respected, but those in the current table connected to the numerical feature are ignored.</td>
</tr>
<tr>
<td>evaluateToStringArray2D</td>
<td>Evaluates the given entity, a Derived Value, and returns the nonparameter column part of the potentially complex valued table that is produced as a string matrix. All settings in the numerical feature are respected, but those in the current table connected to the numerical feature are ignored.</td>
</tr>
<tr>
<td>useResultsTable</td>
<td>Shows the values from the tableFeature in the resultsTable form object.</td>
</tr>
<tr>
<td>getChoiceList</td>
<td>Returns an object of the type ChoiceList, representing a choice list node under the declarations branch. The type ChoiceList has associated methods that make it easy to change values and display names, see the Application Programming Guide.</td>
</tr>
<tr>
<td>setFormObjectEnabled</td>
<td>Sets the enable state for the form object specified by the name or name path.</td>
</tr>
<tr>
<td>setFormObjectVisible</td>
<td>Sets the visible state for the form object specified by the name or name path.</td>
</tr>
<tr>
<td>setFormObjectText</td>
<td>Sets the text for the form object specified by the name or name path in the second argument. This method throws an error if it is impossible to set a text for the specified form object.</td>
</tr>
<tr>
<td>setFormObjectEditable</td>
<td>Sets the editable state for the form object specified by the name or name path. This functionality is only available for text field objects.</td>
</tr>
<tr>
<td>setMenuBarItemEnabled</td>
<td>Sets the enable state for the menu bar item specified by the name or name path (from the menu bar) in the first argument.</td>
</tr>
<tr>
<td>setMainToolbarItemEnabled</td>
<td>Sets the enable state for the main toolbar item specified by the name or name path (from the main toolbar) in the first argument.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>setFileMenuItemEnabled</code></td>
<td>Sets the enable state for the file menu item specified by the name or name path (from the file menu) in the first argument.</td>
</tr>
<tr>
<td><code>setRibbonItemEnabled</code></td>
<td>Sets the enable state for the ribbon item specified by the name or name path (from the main window) in the first argument.</td>
</tr>
<tr>
<td><code>setToolbarItemEnabled</code></td>
<td>Sets the enable state for the toolbar form object item specified by the name or name path in the first argument.</td>
</tr>
<tr>
<td><code>useView</code></td>
<td>Applies a view to the graphics contents given by the name or name path in the second argument.</td>
</tr>
<tr>
<td><code>resetView</code></td>
<td>Resets the view to its initial state in the graphics contents given by the name or name path in the second argument.</td>
</tr>
<tr>
<td><code>getView</code></td>
<td>Returns the view currently used by the graphics contents given by the name or name path in the second argument.</td>
</tr>
<tr>
<td><code>setWebPageSource</code></td>
<td>Sets the source for the form object specified by the name or name path in the first argument.</td>
</tr>
<tr>
<td><code>getScreenHeight</code></td>
<td>Returns the height in pixels of the primary screen on the client system, or of the browser window if Web Client is used.</td>
</tr>
<tr>
<td><code>getScreenWidth</code></td>
<td>Returns the width in pixels of the primary screen on the client system, or of the browser window if Web Client is used.</td>
</tr>
</tbody>
</table>
**GUI Command Methods**

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearAllMeshes</td>
<td>Clears all meshes.</td>
</tr>
<tr>
<td>clearAllSolutions</td>
<td>Clears all solutions.</td>
</tr>
<tr>
<td>exit</td>
<td>Exits the application.</td>
</tr>
<tr>
<td>fileOpen</td>
<td>Opens a file with the associated program on the client.</td>
</tr>
<tr>
<td>fileSaveAs</td>
<td>Downloads a file to the client. See also the section “File Methods”.</td>
</tr>
<tr>
<td>printGraphics</td>
<td>Prints the given graphics object.</td>
</tr>
<tr>
<td>saveApplication</td>
<td>Saves the application.</td>
</tr>
<tr>
<td>saveApplicationAs</td>
<td>Saves the application under a different name. (Or as an MPH file.)</td>
</tr>
<tr>
<td>scenelight</td>
<td>Toggles scene light in the given graphics object.</td>
</tr>
<tr>
<td>transparency</td>
<td>Toggles transparency in the given graphics object.</td>
</tr>
<tr>
<td>zoomExtents</td>
<td>Makes the entire model visible in the given graphics object.</td>
</tr>
</tbody>
</table>

**Debug Method**

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>debugLog</td>
<td>Prints the value of an input argument to the Debug Log window. The input argument can be a scalar, 1D array, or 2D array of the types string, double, integer, or Boolean.</td>
</tr>
</tbody>
</table>

**Methods for External C Libraries**

**EXTERNAL METHOD**

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>external</td>
<td>Returns an interface to an external C (native) library given by the name of the library feature. The External class uses the Java Native Interface (JNI) framework. For more information, see the Application Programming Guide.</td>
</tr>
</tbody>
</table>

**METHODS RETURNED BY THE EXTERNAL METHOD**

The external method returns an object of type `External` with the following

294 |
methods:

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>invoke</td>
<td>Invokes a named native method in the library with the supplied arguments.</td>
</tr>
<tr>
<td>invokeWideString</td>
<td>Invokes the named native method in the library with the supplied arguments.</td>
</tr>
<tr>
<td>close</td>
<td>Releases the library and frees resources. If you do not call this method, it is automatically invoked when the external library is no longer needed.</td>
</tr>
</tbody>
</table>
### Progress Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>setProgressInterval</td>
<td>Sets a progress interval to use for the top-level progress and display message at that level. Calling this method implicitly resets any manual progress previously set by calls to <code>setProgress()</code>.</td>
</tr>
<tr>
<td>setProgress</td>
<td>Sets a value for the user-controlled progress level.</td>
</tr>
<tr>
<td>resetProgress</td>
<td>Removes all progress levels and resets progress to 0 and the message to an empty string.</td>
</tr>
<tr>
<td>showIndeterminatePr</td>
<td>Shows a progress dialog box with an indeterminate progress bar, given <code>message</code>, and an optional cancel button.</td>
</tr>
<tr>
<td>ogress</td>
<td></td>
</tr>
<tr>
<td>showProgress</td>
<td>Shows a progress dialog box with an optional cancel button, optional model progress, and one or two levels of progress information.</td>
</tr>
<tr>
<td>closeProgress</td>
<td>Closes the currently shown progress dialog box.</td>
</tr>
<tr>
<td>startProgress</td>
<td>Resets the value of a given progress bar form object name to 0.</td>
</tr>
<tr>
<td>setProgressBar</td>
<td>Sets the value of a given progress bar form object name in the range 0–100 and the associated progress message.</td>
</tr>
</tbody>
</table>

### Date and Time Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentDate</td>
<td>Returns the current date as a string (formatted according to the server’s defaults) for the current date.</td>
</tr>
<tr>
<td>currentTime</td>
<td>Returns the current time as a string (not including date and formatted according to the server’s defaults).</td>
</tr>
<tr>
<td>formattedTime</td>
<td>Returns a formatted time using the given format. The format can either be a time unit or text describing a longer format.</td>
</tr>
<tr>
<td>sleep</td>
<td>Sleep for a specified number of milliseconds.</td>
</tr>
<tr>
<td>timeStamp</td>
<td>Current time in milliseconds since midnight, January 1, 1970 UTC.</td>
</tr>
<tr>
<td>getExpectedComputa</td>
<td>Returns a string describing the approximate computation time of the application. The string can be altered by the method</td>
</tr>
<tr>
<td>tionTime</td>
<td><code>setExpectedComputationTime</code>.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>setLastComputationTime</code></td>
<td>Set the last computation time, overwriting the automatically generated time. You can use the <code>timeStamp</code> method to record time differences and then set the measured time in ms (a long integer).</td>
</tr>
<tr>
<td><code>getLastComputationTime</code></td>
<td>Returns the last computation time in the given format. The format can either be a time unit or text describing a longer format. This format is localized and the output is translated to the current language setting.</td>
</tr>
</tbody>
</table>
### License Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>getLicenseNumber</td>
<td>Returns a string with the license number for the current session. Example: licensenumber=getLicenseNumber()</td>
</tr>
</tbody>
</table>

### Conversion Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>toBoolean</td>
<td>Converts strings and string arrays to Booleans. (&quot;true&quot; returns true, all other strings return false).</td>
</tr>
<tr>
<td>toDouble</td>
<td>Converts strings and string arrays to doubles.</td>
</tr>
<tr>
<td>toInt</td>
<td>Converts strings and string arrays to integers.</td>
</tr>
<tr>
<td>toString</td>
<td>Converts Booleans, integers, and doubles, including arrays, to strings.</td>
</tr>
</tbody>
</table>

### Array Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>getColumn</td>
<td>Returns a string, double, integer, or Boolean array for a specified column in a 2D array (matrix). This is, for example, useful when values have been read from a file and only certain columns should be shown in a table.</td>
</tr>
<tr>
<td>getSubMatrix</td>
<td>Returns a rectangular submatrix of an input matrix. Available for string, double, integer, or Boolean 2D arrays.</td>
</tr>
<tr>
<td>insert</td>
<td>Inserts one or more elements in an array and returns the expanded array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>append</td>
<td>Adds one or more elements to the end of an array and returns the expanded array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>remove</td>
<td>Removes one or more elements from an array and returns the shortened array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>insertRow</td>
<td>Inserts one or more rows into a rectangular 2D array and returns the expanded array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>appendRow</td>
<td>Adds one or more rows to the end of a rectangular 2D array and returns the expanded array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>removeRow</td>
<td>Removes one or more rows from a 2D array and returns the reduced array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>insertColumn</td>
<td>Adds one or more columns into a rectangular 2D array and returns the expanded array. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>appendColumn</td>
<td>Adds one or more columns at the end of a rectangular 2D array and returns the expanded array. Available for string, double, integer; or Boolean arrays.</td>
</tr>
<tr>
<td>removeColumn</td>
<td>Removes one or more columns from a rectangular 2D array and returns the smaller array. Available for string, double, integer; or Boolean arrays.</td>
</tr>
<tr>
<td>matrixSize</td>
<td>Returns the number of rows and columns of a matrix as an integer array of length 2. Available for string, double, integer; or Boolean arrays.</td>
</tr>
</tbody>
</table>
### String Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>concat</td>
<td>Concatenates a given array or matrix of strings into a single string using the given separators.</td>
</tr>
<tr>
<td>contains</td>
<td>Returns true if a given string array contains a given string.</td>
</tr>
<tr>
<td>find</td>
<td>Returns an array with the indices to all occurrences of a string in a string array.</td>
</tr>
<tr>
<td>findIn</td>
<td>Returns the index to the first occurrence of a string in a string array or the first occurrence of a substring in a string.</td>
</tr>
<tr>
<td>length</td>
<td>Returns the length of a string.</td>
</tr>
<tr>
<td>replace</td>
<td>Returns a string where a string has been replaced with another string.</td>
</tr>
<tr>
<td>split</td>
<td>Returns an array of strings by splitting the given string at a given separator.</td>
</tr>
<tr>
<td>substring</td>
<td>Returns a substring with the given length starting at the given position.</td>
</tr>
<tr>
<td>unique</td>
<td>Returns an array of strings with the unique values in the given array of strings.</td>
</tr>
</tbody>
</table>

### Collection Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy</td>
<td>Returns a copy of the given array or matrix. Available for string, double, integer, or Boolean arrays.</td>
</tr>
<tr>
<td>equals</td>
<td>Returns true if all elements in the given array are equal and they have the same number of elements. Available for string, double, integer, or Boolean arrays. For doubles, comparisons are made using a relative tolerance.</td>
</tr>
<tr>
<td>sort</td>
<td>Sorts the given array. Note: The array is sorted in place. Available for string, double, or integer arrays.</td>
</tr>
<tr>
<td>merge</td>
<td>Returns an array with all of the elements merged from the given arrays. Available for string, double, or integer arrays.</td>
</tr>
</tbody>
</table>

### With, Get, and Set Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>with</td>
<td>Used to make code more compact.</td>
</tr>
<tr>
<td>endwith</td>
<td>The ending of a with statement.</td>
</tr>
<tr>
<td>set</td>
<td>Sets a Boolean, integer, double, or string property value. Allows for a scalar, array, or matrix property.</td>
</tr>
<tr>
<td>NAME</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>setIndex</td>
<td>Sets a string, double, or integer property value for a matrix or vector at a given index.</td>
</tr>
<tr>
<td>getIntArray</td>
<td>Gets an integer vector property.</td>
</tr>
<tr>
<td>getIntMatrix</td>
<td>Gets an integer matrix property.</td>
</tr>
<tr>
<td>getBoolean</td>
<td>Gets a Boolean property.</td>
</tr>
<tr>
<td>getBooleanArray</td>
<td>Gets a Boolean vector property.</td>
</tr>
<tr>
<td>getBooleanMatrix</td>
<td>Gets a Boolean matrix property.</td>
</tr>
<tr>
<td>getDouble</td>
<td>Gets a double property.</td>
</tr>
<tr>
<td>getString</td>
<td>Gets a string scalar, vector, or matrix property.</td>
</tr>
<tr>
<td>getDoubleArray</td>
<td>Gets a double vector property or parameter.</td>
</tr>
<tr>
<td>getDoubleMatrix</td>
<td>Gets a double matrix property or parameter.</td>
</tr>
<tr>
<td>getStringArray</td>
<td>Gets a string vector property or parameter.</td>
</tr>
<tr>
<td>getStringMatrix</td>
<td>Gets a string matrix property or parameter.</td>
</tr>
<tr>
<td>getDblStringArray</td>
<td>Returns the value as a matrix of strings.</td>
</tr>
<tr>
<td>getInt</td>
<td>Gets an integer property.</td>
</tr>
<tr>
<td>get</td>
<td>Returns a variable expression.</td>
</tr>
<tr>
<td>descr</td>
<td>Returns a variable description.</td>
</tr>
</tbody>
</table>
Appendix F — Guidelines for Building Applications

General Tips
• Include reports to files with input data and corresponding output data.
• Make it intuitive. Provide help, hints, and documentation as necessary.
• Make it foolproof: “Safe I/O”, “Reset to default data”, etc.
• Save a thumbnail image with the model.
• Include a description text (It will be visible in the COMSOL Server library).
• Test the application on the computer platforms for which it is intended.
• Be minimalistic. From the developer’s point of view, it is much easier to make sure logic works, organize, debug, maintain, and further develop the app. From a user’s point of view, it is easier to use the application. The minimalistic approach requires more care while developing but much less maintenance later on and much higher adoption among users.
• Embed libraries in the model if they are of manageable size.
• Display the expected computation time and, after the computation, the actual computation time.
• When a computation is canceled, output data from the previous computation should be cleared.
• Password protect as needed. (Remember: No one can help you if you forget the password.)

Methods
• Do not create more methods than necessary.
  Fewer methods give you a shorter list of methods to browse through when looking for something. Fewer methods usually mean fewer lines of code to worry about.
  - If several methods you wrote do essentially the same thing, consider merging them into one method and dealing with the different cases by input arguments.
  - Do not create a method if it is only called from one place. Insert the code right into that place instead.
• Create a local method if it is only used in a form, or triggered by a form event or a form object event.
• Give methods descriptive names and name them so that similar methods are grouped together when sorted alphabetically. You will have less to
remember and you will find what you are looking for easier. Long names are better than hard-to-understand short names.
Method naming examples:
- Start all methods that do not deliver any output by p (p for procedure).
- Start all methods that deliver output with f (f for function).
- Start all menu item methods with m (m for menu).
- Start a method that you will visit frequently with a to make it appear first in the list.
- Start all your plot methods with Plot (mPlotMesh, mPlotResults, for menu item methods).

- The points above apply to method code as well: be minimalistic, use as few lines of code and variables as possible, use descriptive names for variables, use long names instead of hard-to-understand short names, and optimize code to run efficiently.
- The above points apply to declarations as well: use good names, don’t use more than necessary, and declare variables where they are used (in forms and methods or in the model).

**Forms**
- Do not create more forms than necessary.
- Give forms descriptive names. Same reasoning as for methods.
- Make good use of the many different types of form objects. Some are good for some things, while some are good for others.
- Do not insert more form objects than necessary. Too many options for input data may make the application hard to use. Too much output data makes it hard to find important information.
- Insert a text field for the user to leave comments to save with the user’s set of input and output data when saving the application.
- Consider inserting a button with a method to reset to default data.
- Apply “Safe I/O”:
  - For input fields, alert the user about input data that is out of bounds. You can do that either by an alert triggered by an On Data Change event for an input field, or by setting limits in the form objects settings window, which then sets hard limits. In a method generating the alert, you may just warn the user and then allow the input data if the user chooses to go ahead anyway.
  - On output fields, give the precision that makes sense. If current results are not based on current input data, show it. If the computation failed, show it.
• Include tooltips, help, documentation, hints, and comprehensive reports.

• Provide the user with information about how long it takes to run the simulation with default input data on a typical computer. It could be seconds, hours, or even days depending on the application, so that is something the user would like to know before hitting the compute button. Consider playing a sound to alert the user when the computation has finished. The user may be doing something else while waiting for results. (Sending an email message with a report to the user or some other place when the computation is done may be a better alternative if the computation is really long.)

• Spend some time on the layout of a form. A good-looking form makes it easier and more fun to use the application.

• Consider setting keyboard shortcuts for buttons and menu items.
Appendix G — The Application Library Examples

In the Application Libraries, you can find example applications that showcase the capabilities of the Application Builder. They are collected in folders with the name Applications and are available for many of the add-on products. You can edit these applications and use them as a starting point or inspiration for your own application designs. Each application contains documentation (PDF) describing the application and an option for generating a report.

Below is a partial list of the available application examples organized as they appear in the Application Libraries tree.

</tbody>
</table>
The following sections highlight the example applications listed in the table above. The highlighted applications exemplify a variety of important Application Builder features, including the use of animations, email, optimization, parameter estimation, tables, and the import of experimental data.

**Beam Subjected to Traveling Load**

This application simulates the transient response of a beam that is placed on several equidistant supports and is subjected to a traveling load. The purpose of the application is to analyze the response of the bridge when vehicles pass over it. It is observed that for a bridge with given geometric and material properties, certain vehicular speeds cause resonance in the bridge and it undergoes high amplitude...
oscillation. In the application, a 2D plane stress approximation is assumed to model the beam. The beam is made of concrete.

The application demonstrates the use of animation and sliders. The first slider displays deformation versus load position and the second slider shows the time evolution of the displacement. This application does not require any add-on products.

Helical Static Mixer
The purpose of this application is to demonstrate the use of geometry parts and parameterized geometries. In addition, the application can be used to estimate the degree of mixing in a system including one to five helical blades, typically for mixing of monomers and initiators in polymerization reactions. The application is limited to Newtonian liquids, which is a good approximation in the cases where polymerization is negligible in the mixer itself. The application demonstrates the
The use of form collections of the type **tiled or tabbed**. This application does not require any add-on products.

**Transmission Line Calculator**

Transmission lines are used to guide waves of alternating current and voltage at radio frequencies. Transmission lines exist in a variety of forms, many of which are adapted for easy fabrication and employment in printed circuit board designs. They are key elements in most modern electronic devices and are used to carry information, at minimal loss and distortion, from one place to another within a device and between devices.

This application provides predefined user interfaces for computing the transmission line parameters $R$, $L$, $G$, and $C$, as well as $\gamma$ and $Z_0$ for parameterized cross sections of some common transmission line types:

- Coaxial line
- Twin lead
- Microstrip line
- Coplanar waveguide (CPW)
Plots of the geometry, mesh, electric potential, electric field line, and magnetic flux lines are also provided. This application does not require any add-on products.

**Tubular Reactor**

With this application, students in chemical engineering can model a nonideal tubular reactor, including radial and axial variations in temperature and composition, and investigate the impact of different operating conditions. The process described by the application is the exothermic reaction of propylene oxide with water to form propylene glycol.

The application also exemplifies how teachers can build tailored interfaces for problems that challenge the students’ imaginations. The model and exercise are originally described in Scott Fogler’s *Elements of Chemical Reaction Engineering*.

The mathematical model consists of an energy balance and a material balance described in an axisymmetric coordinate system. The students can change the activation energy of the reaction, the thermal conductivity, and the heat of reaction in the reactor. The resulting solution gives the axial and radial conversion as well as temperature profiles in the reactor. For some data, the results from the
simulation are not obvious, which means that the interpretation of the model results also becomes a problem-solving exercise.

Note that you may also have the application send an email when the computation is ready by selecting the email check box and entering an email address. This sends a report with the settings and the computed results. The functionality can be used by students to send the results to a supervisor. For computations that take a longer time to compute, this functionality may be of great use. For example, you can start a simulation and leave the office or laboratory, then get the full report from the application when the computation is done, which you can access on the road or wherever you have access to email. This application does not require any add-on products.

Tuning Fork
This application computes the resonant frequency of a tuning fork with a user-defined prong length. Alternatively, you can give a user-defined target frequency and the application will find the corresponding prong length. The prong and handle radii are taken from a commercially available tuning fork.
The model embedded in the application is defined using the Solid Mechanics interface included in COMSOL Multiphysics and does not require any add-on products. The prong length search algorithm is a secant method. At the end of the computation, the built-in method playSound is used to produce a sine wave sound at the computed frequency. For more background theory, see the Application Library documentation for the model tuning_fork.mph.

**Induction Heating of a Steel Billet**

This application can be used to design a simple induction heating system for a steel billet, consisting of one or more electromagnetic coils through which the billet is moved at a constant velocity. The coils are energized with alternating currents and induce eddy currents in the metallic billet, generating heat due to Joule heating. The billet cross section, coil number, placement, size, initial and ambient temperatures, and individual coil currents can all be specified as inputs. After the solution has been computed, the application displays 3D plots of the billet temperature during processing, the induced electric current density, and a 2D plot of the temperature at the outlet cross section. Finally, the application computes
numerical data for the expected temperature ranges in the billet and the power balance of the system.

**Touchscreen Simulator**

This application computes the capacitive response of a small touchscreen in the presence of a human finger phantom. This information can be used by an electronic circuit to derive the position of the finger. In the application, the
position and orientation of the finger are controlled via input parameters, and the resulting capacitance matrix is computed as output.

Absorptive Muffler Designer
The purpose of this application is to study and design a simple resonant muffler with a porous lining. Mufflers are used to attenuate noise emitted by, for example, a combustion engine or an HVAC system and should typically perform well in a specific frequency range. The measure of the attenuation is called the transmission loss (TL) and gives the damping in dB as a function of frequency. The transmission loss depends on the geometry of the muffler and on the characteristics of porous and fibrous materials that can be placed in the system. This application is used to study the results of modifying the dimensions of a muffler; the ambient working conditions; and the material properties of the porous liner — that is, how changes influence the transmission loss of the system. This application is an example of a “dynamic specification sheet” for a given muffler model. A sales engineer can bring this type of application to customers and show them the performance of a custom muffler designed specifically for them. A muffler may, for example, be designed to be placed in a vehicle with spatial...
constraints. In this case, the performance can be readily visualized and different options can be investigated together with the customer.

Acoustic Reflection Analyzer
This application analyzes the reflections of plane waves off a water-sediment interface. The reflection and absorption coefficients are determined as functions of the angle of incidence and the frequency. Moreover, the random-incidence absorption coefficient, or diffuse field absorption coefficient, is calculated based on the simulated data. The material properties of the fluid, in this case water, and the
The goal with this application is to explain experimental electrochemical impedance spectroscopy measurements (EIS) and to show how you can use the model and the measurements to estimate the properties of lithium-ion batteries. The application takes experimental data from EIS measurements as input, simulates these measurements, and then runs a parameter estimation based on the experimental data.

The control parameters are the exchange current density, the resistivity of the resistive layer on the particles, the double-layer capacitance of NCA, and the double-layer capacitance of the carbon support in the positive electrode. The fitting is done to the measured impedance of the positive electrode at frequencies ranging from 10 mHz to 1 kHz.
The application demonstrates loading experimental data on the comma-separated values (CSV) file format and utilizes the Optimization Module for parameter estimation.

**Inkjet**

The purpose of this application is to adapt the shape and operation of an inkjet nozzle for a desired droplet size, which depends on the contact angle, surface tension, viscosity, and density of the injected liquid.
The results also reveal whether the injected volume breaks up into several droplets before merging into a final droplet at the substrate.

**Water Treatment Basin**

The purpose of the Water Treatment Basin application is to exemplify the use of applications for modeling turbulent flow in liquids in 3D. An interesting aspect of the application is that it also accounts for the material balance of a solute in a solution. This solute reacts in a first-order reaction, a common type of reaction for describing the decay of highly diluted chemical species. This application also shows how to use fully parameterized geometries and cumulative selections for modeling turbulent flows.

The application can be used as a starting point for your own application for modeling the turbulent steady flow of liquids with reactions of highly diluted solutes.
The exemplified system is a chlorination basin in a water treatment process.

**Biosensor Design**

A flow cell in a biosensor contains an array of micropillars used to detect biomolecules. The pillars are coated with an active material that selectively adsorbs biomolecules in the sample stream. These biomolecules then react on the surface. This application allows the user to change the design of the sensor by altering parameters such as pillar diameter, grid spacing, and inlet velocity to investigate how the design affects the detection results. The geometry and operating conditions have a great impact on the signal strength and diffuseness.
Also, manufacturing constraints, set by a minimum distance between pillars, are reported in the application.

**Membrane Dialysis**

This application simulates the contaminant concentration within a bloodstream that is purified within a membrane dialysis device. The modeled dialysis device is made of a hollow fiber module, where the walls of the hollow fibers act as a membrane for removal of the contaminant. Within the fibers, the dialysate flows, whereas on the outside, the permeate passes. Through variation of the input
parameters, the application can examine approaches on how to maximize the contaminant removal within the device.

**Concentric Tube Heat Exchanger**

Dimensioning quantities are the first indicators of the behavior of a heat exchanger. This application aims to compute these quantities for a given configuration.

The example application studies the case of two concentric tubes separating two distinct fluids. The fluids can run either in counterflow or in parallel flow. Both tubes and fluids can be customized through the user interface.

After the computation, the temperature profile and several quantities are displayed. Additional inputs are fluid properties such as available volume and mass,
compactness (the ratio of exchanged surface to heat exchanger volume), and material properties.

**Heat Sink with Fins**

Heat sinks are usually benchmarked with respect to their ability to dissipate heat for a given fan curve. One possible way to carry out this type of experiment is to place the heat sink in a rectangular channel with insulated walls. The temperature and pressure at the channel’s inlet and outlet, as well as the power required to keep the heat sink base at a given temperature, is then measured. Under these conditions, it is possible to estimate the amount of heat dissipated by the heat sink and the pressure loss over the channel.

The purpose of this application is to investigate of benchmark experiments using modeling and simulation. For example, the amount of heat dissipated may increase with the number of fins until the fins create such a large obstruction to the flow that the flow decreases and lowers the amount of heat dissipated. This implies that for a given total pressure loss over the channel, there may be optimal
dimensions and a number of fins that give the highest cooling power. This application enables you to perform such investigations.

**Equivalent Properties of Periodic Microstructures**

Periodic microstructures are frequently found in composite materials, such as carbon fibers and honeycomb structures. They can be represented by a unit cell repeated along three directions of propagation. To reduce computational costs, simulation may replace all of the details of a composite material with a homogeneous domain with equivalent properties.

This application computes equivalent properties from the geometrical configuration and the material properties of a unit cell. It offers a choice between nine parameterizable unit cells and a list of 13 predefined materials. Extending this application to additional parallelepiped unit cells or adding other materials is straightforward.

In diffusion-like equations such as the heat equation, the equivalent diffusion coefficient takes the general form of a tensor.

In this application, the following material properties are computed from a selected unit cell shape with given materials in the different regions of the unit cell:

- Density
- Heat capacity at constant pressure
- Thermal conductivity
The built-in unit cell library in this application includes several widely used cell types, such as parallel stacked layers, fiber-reinforced composites, or honeycomb structures. Once the geometry is set, the physics consists of periodic heat conditions at opposite boundaries of the cell.

**Red Blood Cell Separation**

Dielectrophoresis (DEP) is a phenomenon in which a force is exerted on a dielectric particle when it is subjected to a nonuniform electric field. The electric field induces a polarization in the particles, which are then subject to a DEP force that is proportional to the gradient of the electric potential. The DEP force is sensitive to the size, shape, and dielectric properties of the particles. This allows DEP to be used to separate different kinds of particles. One application of this process is in the field of bioengineering, where DEP can be used to separate different kinds of cells from a mixture. This example application shows how red blood cells can be selectively filtered from a blood sample in order to isolate red blood cells from platelets. This is useful because platelets cause blood
to clot, which can lead samples contaminated with platelets to be unsuitable for subsequent testing once a clot has formed.

**Mixer**

The purpose of the Mixer application is to provide a user-friendly interface where scientists, process designers, and process engineers can investigate the influence that vessel, impeller, and operational conditions have on the mixing efficiency and power required to drive the impellers. The application can be used to understand and optimize the design and operation of the mixer for a given fluid. But, perhaps most importantly, the Mixer application can be used as a starting point for your own application for the modeling and simulation of mixers and reactors.

The application demonstrates how parts and cumulative selections can be used to automatically set domain and boundary settings in the embedded models. These
settings can be created automatically, even when the choices made by an application user create very diverse geometries.
**Truck Mounted Crane Analyzer**

Many trucks are equipped with cranes for load handling. Such cranes have a number of hydraulic cylinders that control the crane’s motion, and several mechanisms.

In this application, a rigid-body analysis of a crane is performed in order to find the payload capacity for the specified orientation and extension of the crane. This application also provides the usage of hydraulic cylinders and highlights the limiting cylinder. The capacity of the hydraulic cylinders can be modified in order to improve the payload capacity and the usage of the cylinders.

**Laminar Static Particle Mixer Designer**

In static mixers, also called motionless or in-line mixers, a fluid is pumped through a pipe containing stationary blades. This mixing technique is particularly well suited for laminar flow mixing because it generates only small pressure losses in this flow regime. This application studies the flow in a twisted-blade static mixer. It evaluates the mixing performance by calculating the trajectory of suspended particles through the mixer. The application computes the static mixing of one species dissolved in a solvent at room temperature. You can study the effect of fluid
and particle properties as well as the stationary blades’ configuration on the particle mixing.

**Distributed Bragg Reflector Filter**

A distributed Bragg reflector (DBR) consists of alternating layers of two materials. Each material has a different refractive index, resulting in a repeating pattern of high and low refractive indices in the direction perpendicular to the DBR layers. As light propagates through this structure, reflections occur at each interface between the layers. Interference effects between the multiple reflected waves cause the reflectivity of the DBR to be highly wavelength dependent. The main advantage of DBRs over ordinary metallic mirrors is that DBRs can be engineered to have custom reflectances at selected wavelengths.
This application can be used to study the reflectance from a simple optical notch filter, based on a cavity sandwiched between two distributed Bragg reflectors.

**Frequency Selective Surface Simulator**

Frequency selective surfaces (FSS) are periodic structures that generate a bandpass or a bandstop frequency response. This application simulates a user-specified periodic structure chosen from the built-in unit cell types. It provides five popular FSS unit cell types, with two predefined polarizations and propagation at normal incidence.
The analysis includes the reflection and transmission spectra, the electric field norm on the top surface of the unit cell, and the dB-scaled electric field norm shown on a vertical cut plane in the unit cell domain.

**Microstrip Patch Antenna Array Synthesizer**
This application simulates a single slot-coupled microstrip patch antenna that is fabricated on a multilayered low-temperature cofired ceramic (LTCC) substrate. Results include the far-field radiation pattern of the antenna array and its directivity. The far-field radiation pattern is approximated by multiplying the array factor and the single antenna radiation pattern to perform an efficient far-field analysis without simulating a complicated full array model. Phased antenna array prototypes for 5G mobile networks can easily be evaluated with the default input
frequency, 30 GHz. The application also demonstrates an animation where the camera is moved around the antenna.

Wavelength Tunable LED

Blue LEDs are interesting because of their use in modern high-efficiency lighting. Due to their large bandgap energy, gallium nitrides are widely used for generating blue light. This application simulates the emission properties of a gallium-nitride-based light-emitting diode.

The material used in the active region of the device is In$_x$Ga$_{1-x}$N, which contains a blend of both gallium and indium where the fraction of indium is given by $x$. The bandgap of this optically active region can be controlled by varying the composition of the material via changing the indium fraction. Because pure InN and GaN emit in the infrared and ultraviolet parts of the spectral range respectively, it is possible to tune the emission energy of In$_x$Ga$_{1-x}$N across the entire visible spectrum using this technique.

This application enables the indium fraction and operating voltage of the device to be controlled. The current, emission intensity, electroluminescence spectrum, and internal quantum efficiency of the device can then be computed. Either a single operating voltage or a range of voltages can be input. If a range of voltages
is input, the current-voltage curve is also calculated, which allows the turn-on voltage of the device to be determined. This application uses methods extensively.

**Beam Section Calculator**

This application computes the beam section properties for a designated steel beam section. It also allows for computing the detailed stress distribution over the cross section given a set of forces and moments acting on it. A broad range of American and European standard beams are available. With a license for the LiveLink™ for Excel® product, all input and results data is displayed in a table that can be exported to an Excel® file. It is possible to edit the Excel® workbook that contains the beam dimensions data and reimport this data back into the application.
Truss Tower Buckling

Buckling analysis is the search for the critical compressive load beyond which structures become unstable. This application can simulate the buckling of a truss tower under vertical compressive loads. The tower can optionally be supported by guy wires. The purpose of the application is to compute and analyze the buckling load for towers under different conditions of geometry, i.e., various tower heights, cross-sectional area, as well as different materials. The application takes into
account the effect of dead load (self-weight of truss and supporting guy wires and their pretension) while performing the computation.

**Fiber Simulator**

This application performs mode analyses on concentric circular dielectric layer structures. Each layer is described by an outer diameter and the real and imaginary parts of the refractive index. The refractive index expressions can include a dependence on both wavelength and radial distance. Thus, the simulator can be used for analyzing both step-index fibers and graded-index fibers. These fibers can
have an arbitrary number of concentric circular layers. Computed results include group delay and dispersion coefficient.

*Plasmonic Wire Grating*

This application computes diffraction efficiencies for the transmitted and reflected waves \( (m = 0) \) and the first and second diffraction orders \( (m = \pm 1 \text{ and } \pm 2) \) as functions of the angle of incidence for a wire grating on a dielectric substrate. The incident angle of a plane wave is swept from normal incidence to grazing.
incidence. The application also shows the electric field norm plot for multiple grating periods for a selected angle of incidence.
